

## Summary

The Xilinx<sup>®</sup> Virtex<sup>®</sup> UltraScale+<sup>™</sup> FPGAs are available in -3, -2, -1 speed grades, with -3E devices having the highest performance. The -2LE devices can operate at a  $V_{CCINT}$  voltage at 0.85V or 0.72V and provide lower maximum static power. When operated at  $V_{CCINT} = 0.85V$ , using -2LE devices, the speed specification for the L devices is the same as the -2I speed grade. When operated at  $V_{CCINT} = 0.72V$ , the -2LE performance and static and dynamic power is reduced.

DC and AC characteristics are specified in extended (E) and industrial (I) temperature ranges. Except the operating temperature range or unless otherwise noted, all the DC and AC electrical parameters are the same for a particular speed grade (that is, the timing characteristics of a -1 speed grade extended device are the same as for a -1 speed grade industrial device). However, only selected speed grades and/or devices are available in each temperature range.

All supply voltage and junction temperature specifications are representative of worst-case conditions. The parameters included are common to popular designs and typical applications.

This data sheet, part of an overall set of documentation on the Virtex UltraScale+ FPGAs, is available on the Xilinx website at [www.xilinx.com/documentation](http://www.xilinx.com/documentation).

**Notes:**

- All voltages are relative to GND.
- For the design of the power distribution system consult the *UltraScale Architecture PCB Design User Guide (UG583)*.
- V<sub>CCINT\_IO</sub> must be connected to V<sub>CCBRAM</sub>.
- For V<sub>CCO\_0</sub>, the minimum recommended operating voltage for power on and during configuration is 1.425V. After configuration, data is retained even if V<sub>CCO</sub> drops to 0V.
- Includes V<sub>CCO</sub> of 1.0V, 1.2V, 1.35V, 1.5V, and 1.8V.
- V<sub>CCAUX\_IO</sub> must be connected to V<sub>CCAUX</sub>.
- The lower absolute voltage specification always applies.
- A total of 200 mA per bank should not be exceeded.
- If battery is not used, connect V<sub>BATT</sub> to either GND or V<sub>CCAUX</sub>.
- Each voltage listed requires filtering as described in the *UltraScale Architecture GTy Transceivers User Guide (UG578)*.
- Xilinx recommends measuring the T<sub>j</sub> of a device using the system monitor as described in the *UltraScale Architecture System Monitor User Guide (UG580)*. The system monitor temperature measurement errors (that are described in [Table 62](#)) must be accounted for in your design. For example, when using the system monitor with an external reference of 1.25V, and when the system monitor reports 97°C, there is a measurement error ±3°C. A reading of 97°C is considered the maximum adjusted T<sub>j</sub> (100°C - 3°C = 97°C).
- Devices labeled with the speed/temperature grade of -2LE can operate for a limited time at a junction temperature between 100°C and 110°C. Timing parameters adhere to the same speed file at 110°C as they do below 110°C, regardless of operating voltage (nominal voltage of 0.85V or a low-voltage of 0.72V). Operation up to T<sub>j</sub> = 110°C is limited to 1% of the device lifetime and can occur sequentially or at regular intervals as long as the total time does not exceed 1% of the device lifetime.
- The recommended maximum operating temperature for high-bandwidth memory is 95°C.
- Do not program eFUSE during device configuration (e.g., during configuration, during configuration readback, or when readback CRC is active).

## Power Supply Sequencing

### Power-On/Off Power Supply Sequencing

The recommended power-on sequence is V<sub>CCINT</sub>, V<sub>CCINT\_IO</sub>/V<sub>CBBRAM</sub>, V<sub>CCAUX</sub>/V<sub>CCAUX\_IO</sub>, and V<sub>CCO</sub> to achieve minimum current draw and ensure that the I/Os are 3-stated at power-on. The recommended power-off sequence is the reverse of the power-on sequence. If V<sub>CCINT</sub> and V<sub>CCINT\_IO</sub>/V<sub>CBBRAM</sub> have the same recommended voltage levels, they can be powered by the same supply and ramped simultaneously. V<sub>CCINT\_IO</sub> must be connected to V<sub>CBBRAM</sub>. If V<sub>CCAUX</sub>/V<sub>CCAUX\_IO</sub> and V<sub>CCO</sub> have the same recommended voltage levels, they can be powered by the same supply and ramped simultaneously. V<sub>CCAUX</sub> and V<sub>CCAUX\_IO</sub> must be connected together. V<sub>CCADC</sub> and V<sub>REF</sub> can be powered at any time and have no power-up sequencing requirements.

For devices with HBM, the HBM power supplies can be powered on/off after or in-parallel with the core power supplies. The required power-on sequence is  $V_{CCAUX\_HBM}$  and  $V_{CCINT\_IO}$  followed by  $V_{CC\_HBM}/V_{CC\_IO\_HBM}$ .  $V_{CC\_IO\_HBM}$  must be connected to  $V_{CC\_HBM}$ .  $V_{CCAUX\_HBM}$  must be equal to or higher than  $V_{CC\_HBM}$  at all times. The recommended power-off sequence is the reverse of the power-on sequence.

The recommended power-on sequence to achieve minimum current draw for the GTY transceivers is  $V_{CCINT}$ ,  $V_{MGTAVCC}$ ,  $V_{MGTAVTT}$  OR  $V_{MGTAVCC}$ ,  $V_{CCINT}$ ,  $V_{MGTAVTT}$ . There is no recommended sequencing for  $V_{MGTAVCC}$ . Both  $V_{MGTAVCC}$  and  $V_{CCINT}$  can be ramped simultaneously. The recommended power-off sequence is the reverse of the power-on sequence to achieve minimum current draw. If these recommended sequences are not met, current drawn from  $V_{MGTAVTT}$  can be higher than specifications during power-up and power-down.

## Power Supply Requirements

Table 6 shows the minimum current, in addition to  $I_{CCQ}$  maximum, required by each Virtex UltraScale+ FPGA for proper power-on and configuration. If these current minimums are met, the device powers on after all supplies have passed through their power-on reset threshold voltages. The device must not be configured until after  $V_{CCINT}$  is applied. Once initialized and configured, use the Xilinx Power Estimator (XPE) tools to estimate current drain on these supplies. The XPE spreadsheet tool (download at <http://www.xilinx.com/power>) is also used to estimate power-on current for all supplies.

## DC Input and Output Levels

Values for  $V_{IL}$  and  $V_{IH}$  are recommended input voltages. Values for  $I_{OL}$  and  $I_{OH}$  are guaranteed over the recommended operating conditions at the  $V_{OL}$  and  $V_{OH}$  test points. Only selected standards are tested. These are chosen to ensure that all standards meet their specifications. The selected standards are tested at a minimum  $V_{CCO}$  with the respective  $V_{OL}$  and  $V_{OH}$  voltage levels shown. Other standards are sample tested.

**Notes:**

1. In I/O banks, when LVDS is used with input-only functionality, it can be placed in a bank where the  $V_{CC0}$  levels are different from the specified level only if internal differential termination is not used. In this scenario,  $V_{CC0}$  must be chosen to ensure the input pin voltage levels do not violate the Recommended Operating Condition (Table 2) specification for the  $V_{IN}$  I/O pin voltage.
2.  $V_{OCM}$  and  $V_{ODIFF}$  values are for LVDS\_PRE\_EMPHASIS = FALSE.
3. Maximum  $V_{IDIFF}$  value is specified for the maximum  $V_{ICM}$  specification. With a lower  $V_{ICM}$ , a higher  $V_{IDIFF}$  is tolerated only when the recommended operating conditions and overshoot/undershoot  $V_{IN}$  specifications are maintained.
4. Input common mode voltage for DC coupled configurations. EQUALIZATION = EQ\_NONE (Default).
5. External input common mode voltage specification for AC coupled configurations. EQUALIZATION = EQ\_LEVEL0, EQ\_LEVEL1, EQ\_LEVEL2, EQ\_LEVEL3, EQ\_LEVEL4.

## AC Switching Characteristics

All values represented in this data sheet are based on the speed specifications in the Vivado® Design Suite as outlined in the following table.

Table 16: Speed Specification Version By Device

2018.2.1	Device
1.21	XCVU3P, XCVU7P, XCVU9P, XCVU5P, XCVU11P, XCVU13P
1.03	XCVU31P, XCVU33P, XCVU35P, XCVU37P

Switching characteristics are specified on a per-speed-grade basis and can be designated as Advance, Preliminary, or Production. Each designation is defined as follows:

- **Advance Product Specification:** These specifications are based on simulations only and are typically available soon after device design specifications are frozen. Although speed grades with this designation are considered relatively stable and conservative, some under-reporting might still occur.
- **Preliminary Product Specification:** These specifications are based on complete ES (engineering sample) silicon characterization. Devices and speed grades with this designation are intended to give a better indication of the expected performance of production silicon. The probability of under-reporting delays is greatly reduced as compared to Advance data.

- Product Specification:** These specifications are released once enough production silicon of a particular device family member has been characterized to provide full correlation between specifications and devices over numerous production lots. There is no under-reporting of delays, and customers receive formal notification of any subsequent changes. Typically, the slowest speed grades transition to production before faster speed grades.

## Testing of AC Switching Characteristics

Internal timing parameters are derived from measuring internal test patterns. All AC switching characteristics are representative of worst-case supply voltage and junction temperature conditions.

For more specific, more precise, and worst-case guaranteed data, use the values reported by the static timing analyzer and back-annotate to the simulation net list. Unless otherwise noted, values apply to all Virtex UltraScale+ FPGAs.

## Speed Grade Designations

Since individual family members are produced at different times, the migration from one category to another depends completely on the status of the fabrication process for each device. [Table 17](#) correlates the current status of the Virtex UltraScale+ FPGA on a per speed grade basis.

## Production Silicon and Software Status

In some cases, a particular family member (and speed grade) is released to production before a speed specification is released with the correct label (Advance, Preliminary, Production). Any labeling discrepancies are corrected in subsequent speed specification releases.

Table 18 lists the production released Virtex UltraScale+ FPGA, speed grade, and the minimum corresponding supported speed specification version and Vivado software revisions. The Vivado software and speed specifications listed are the minimum releases required for production. All subsequent releases of software and speed specifications are valid.

	8	187.5	800	187.5	800	187.5	630	187.5	800	Mb/s

**Notes:**

1. Native mode is supported through the [High-Speed SelectIO Interface Wizard](#) available with the Vivado Design Suite. The performance values assume a source-synchronous interface.
2. PLL settings can restrict the minimum allowable data rate. For example, when using the PLL with CLKOUTPHY\_MODE = VCO\_HALF the minimum frequency is PLL\_F<sub>VCOMIN</sub>/2.
3. LVDS receivers are typically bounded with certain applications to achieve maximum performance. Package skews are not included and should be removed through PCB routing.
4. Asynchronous receiver performance is limited to 1300 Mb/s for -3/-2 speed grades and to 1250 Mb/s for -1 speed grades.

1. 1000BASE-X support is based on the *IEEE Standard for CSMA/CD Access Method and Physical Layer Specifications* (IEEE Std 802.3-2008).

The following table provides the maximum data rates for applicable memory standards using the Virtex UltraScale+ FPGA memory PHY. Refer to [Memory Interfaces](#) for the complete list of memory interface standards supported and detailed specifications. The final performance of the memory interface is determined through a complete design implemented in the Vivado Design Suite, following guidelines in the *UltraScale Architecture PCB Design User Guide (UG583)*, electrical analysis, and characterization of the system.

## FPGA Logic Switching Characteristics

The following IOB high-performance (HP) table summarizes the values of standard-specific data input delay adjustments, output delays terminating at pads (based on standard) and 3-state delays.

- T<sub>INBUF\_DELAY\_PAD\_I</sub> is the delay from IOB pad through the input buffer to the I-pin of an IOB pad. The delay varies depending on the capability of the SelectIO input buffer.
- T<sub>OUTBUF\_DELAY\_O\_PAD</sub> is the delay from the O pin to the IOB pad through the output buffer of an IOB pad. The delay varies depending on the capability of the SelectIO output buffer.

- $T_{\text{OUTBUF\_DELAY\_TD\_PAD}}$  is the delay from the T pin to the IOB pad through the output buffer of an IOB pad, when 3-state is disabled. The delay varies depending on the SelectIO capability of the output buffer. In I/O banks, the internal DCI termination turn-on time is always faster than  $T_{\text{OUTBUF\_DELAY\_TD\_PAD}}$  when the DCITERMDISABLE pin is used.

## IOB 3-state Output Switching Characteristics

Table 25 specifies the values of  $T_{OUTBUF\_DELAY\_TE\_PAD}$  and  $T_{INBUF\_DELAY\_IBUFDIS\_O}$ .

- $T_{OUTBUF\_DELAY\_TE\_PAD}$  is the delay from the T pin to the IOB pad through the output buffer of an IOB pad, when 3-state is enabled (i.e., a high impedance state).
- $T_{INBUF\_DELAY\_IBUFDIS\_O}$  is the IOB delay from IBUFDISABLE to O output.
- In I/O banks, the internal DCI termination turn-off time is always faster than  $T_{OUTBUF\_DELAY\_TE\_PAD}$  when the DCITERMDISABLE pin is used.

**Notes:**

1. The input delay measurement methodology parameters for LVDCI/HSLVDCI are the same for LVCMOS standards of the same voltage. Parameters for all other DCI standards are the same for the corresponding non-DCI standards.
2. Input waveform switches between  $V_L$  and  $V_H$ .
3. Measurements are made at typical, minimum, and maximum  $V_{REF}$  values. Reported delays reflect worst case of these measurements.  $V_{REF}$  values listed are typical.
4. Input voltage level from which measurement starts.
5. This is an input voltage reference that bears no relation to the  $V_{REF}/V_{MEAS}$  parameters found in IBIS models and/or noted in Figure 1.
6. The value given is the differential input voltage.

## Output Delay Measurement Methodology

Output delays are measured with short output traces. Standard termination was used for all testing. The propagation delay of the trace is characterized separately and subtracted from the final measurement, and is therefore not included in the generalized test setups shown in Figure 1 and Figure 2.

Figure 1: Single-Ended Test Setup

X16654-072117

Figure 2: Differential Test Setup

X16640-072117

Parameters  $V_{REF}$ ,  $R_{REF}$ ,  $C_{REF}$ , and  $V_{MEAS}$  fully describe the test conditions for each I/O standard. The most accurate prediction of propagation delay in any given application can be obtained through IBIS simulation, using this method:

1. Simulate the output driver of choice into the generalized test setup using values from [Table 27](#).
2. Record the time to  $V_{MEAS}$ .
3. Simulate the output driver of choice into the actual PCB trace and load using the appropriate IBIS model or capacitance value to represent the load.
4. Record the time to  $V_{MEAS}$ .
5. Compare the results of step 2 and step 4. The increase or decrease in delay yields the actual propagation delay of the PCB trace.

T <sub>SAMP_NATIVE_BISC</sub> <sup>3</sup>	60	60	85	85	ps

**Notes:**

1. This parameter indicates the total sampling error of the Virtex UltraScale+ FPGA DDR input registers, measured across voltage, temperature, and process. The characterization methodology uses the MMCM to capture the DDR input registers' edges of operation. These measurements include: CLK0 MMCM jitter, MMCM accuracy (phase offset), and MMCM phase shift resolution. These measurements do not include package or clock tree skew.
2. This parameter is the receive sampling error for RX\_BITSLICE when using dynamic phase alignment.
3. This parameter is the receive sampling error for RX\_BITSLICE when using built-in self-calibration (BISC).

T <sub>INPUT_LOGIC_UNCERTAINTY</sub> <sup>1</sup>	40				ps
T <sub>CAL_ERROR</sub> <sup>2</sup>	24				ps

**Notes:**

1. Input\_logic\_uncertainty accounts for the setup/hold and any pattern dependent jitter for the input logic (input register, IDDRE1, or ISERDESE3).
2. Calibration error associated with quantization effects based on the IDELAY resolution. Calibration must be performed for each input pin to ensure optimal performance.

Parameter	Symbol	Comments/Conditions	Min	Typ	Max	Units
On-chip reference		Ground $V_{REFP}$ pin to AGND, $T_j = -40^{\circ}\text{C}$ to $100^{\circ}\text{C}$	1.2375	1.25	1.2625	V
		Ground $V_{REFP}$ pin to AGND, $T_j = -55^{\circ}\text{C}$ to $125^{\circ}\text{C}$	1.225	1.25	1.275	V

**Notes:**

- ADC offset errors are removed by enabling the ADC automatic offset calibration feature. The values are specified for when this feature is enabled.
- See the Analog Input section in the *UltraScale Architecture System Monitor User Guide (UG580)*.
- When reading temperature values directly from the PMBus interface, the SYSMON has a  $+4^{\circ}\text{C}$  offset due to the transfer function used by the PMBus application. For example, the external REF temperature sensor error's range of  $\pm 3^{\circ}\text{C}$  becomes  $+1^{\circ}\text{C}$  to  $+7^{\circ}\text{C}$  when the temperature is read through the PMBus interface.
- Supply sensor offset and gain errors are removed by enabling the automatic offset and gain calibration feature. The values are specified for when this feature is enabled.
- See the Adjusting the Acquisition Settling Time section in the *UltraScale Architecture System Monitor User Guide (UG580)*.
- Any variation in the reference voltage from the nominal  $V_{REFP} = 1.25\text{V}$  and  $V_{REFN} = 0\text{V}$  will result in a deviation from the ideal transfer function. This also impacts the accuracy of the internal sensor measurements (i.e., temperature and power supply). However, for external ratiometric type applications allowing reference to vary by  $\pm 4\%$  is permitted.
