Preparing for Implementation

About the Vivado Implementation Process

The Xilinx® Vivado® Design Suite enables implementation of UltraScale™ FPGA and Xilinx 7 series FPGA designs from a variety of design sources, including:

- RTL designs
- Netlist designs
- IP centric design flows

Figure 1-1 shows the Vivado tools flow.

Vivado implementation includes all steps necessary to place and route the netlist onto the FPGA device resources, while meeting the design’s logical, physical, and timing constraints.

For more information about the design flows supported by the Vivado tools, see the Vivado Design Suite User Guide: Design Flows Overview (UG892) [Ref 1].

Vivado Implementation Supports SDC and XDC Constraints

The Vivado Design Suite implementation is a timing-driven flow. It supports industry standard Synopsys Design Constraints (SDC) commands to specify design requirements and restrictions, as well as additional commands in the Xilinx Design Constraints format (XDC).
Chapter 1: Preparing for Implementation

Vivado Implementation Sub-Processes

The Vivado Design Suite implementation process transforms a logical netlist and constraints into a placed and routed design, ready for bitstream generation. The implementation process consists of the following sub-processes:

- **Opt Design:**
  Optimizes the logical design to make it easier to fit onto the target Xilinx device.

- **Power Opt Design (optional):**
  Optimizes design elements to reduce the power demands of the target Xilinx device.

- **Place Design:**
  Places the design onto the target Xilinx device.

- **Post-Place Power Opt Design (optional):**
  Additional optimization to reduce power after placement.

- **Post-Place Phys Opt Design (optional):**
  Optimizes logic and placement using estimated timing based on placement. Includes replication of high fanout drivers.

- **Route Design:**
  Routes the design onto the target Xilinx device.

The diagram illustrates the Vivado Design Suite High-Level Design Flow, showing the flow from C Sources and RTL, Netlist, and Constraints to the final IP Packaging.
• Post-Route Phys Opt Design (optional):
  Optimizes logic, placement, and routing using actual routed delays.

• Write Bitstream:
  Generates a bitstream for Xilinx device configuration. Typically, bitstream generation
  follows implementation.

For more information about writing the bitstream, see Vivado Design Suite User Guide: Programming and Debugging (UG908) [Ref 12].

*Note:* The Vivado Design Suite supports Module Analysis, which is the implementation of a part of a design to estimate performance. I/O buffer insertion is skipped for this flow to prevent over-utilization of I/O. For further information, search on “module analysis” in the Vivado Design Suite User Guide: Hierarchical Design (UG905) [Ref 2].

### Multithreading with the Vivado Tools

On multiprocessor systems, Vivado tools use multithreading to speed up certain processes, including DRC reporting, static timing analysis, placement, and routing. The maximum number of simultaneous threads varies, depending on the OS, number of processors, and the particular task. The maximum number of threads by task is:

- DRC reporting: 8
- Static timing analysis: 8
- Placement: 8
- Routing: 8

There is also a general limit that applies to all tasks and is based on the OS. For Windows systems, the limit is 2; for Linux systems the limit is 8. The limit can be changed using a parameter called *general.maxThreads*. To change the limit:

```
Vivado% set_param general.maxThreads <new limit>
```

where the new limit must be an integer from 1 to 8, inclusive. Example: On a Windows system:

```
Vivado% get_param general.maxThreads 2
```

This means all tasks are limited to 2 threads regardless of number of processors or the task being executed. If the system has at least 8 processors, you can set the limit to 8 and allow each task to use the maximum number of threads.

```
Vivado% set_param general.maxThreads 8
```
Chapter 1: Preparing for Implementation

To summarize, the number of simultaneous threads is the minimum of the following:

- Maximum number of processors
- Limit of threads for the task
- General limit of threads

**Tcl API Supports Scripting**

The Vivado Design Suite includes a Tool Command Language (Tcl) Application Programming Interface (API). The Tcl API supports scripting for all design flows, allowing you to customize the design flow to meet your specific requirements.

*Note:* For more information about Tcl commands, see the *Vivado Design Suite Tcl Command Reference Guide* (UG835) [Ref 15], or type `<command> -help`.

---

**Managing Implementation**

The Vivado Design Suite includes a variety of design flows and supports an array of design sources. To generate a bitstream that can be downloaded onto an FPGA device, the design must pass through implementation.

Implementation is a series of steps that takes the logical netlist and maps it into the physical array of the target Xilinx device. Implementation comprises:

- Logic optimization
- Placement of logic cells
- Routing of connections between cells

**Project Mode and Non-Project Modes**

The Vivado Design Suite lets you run implementation with a project file (Project Mode) or without a project file (Non-Project Mode).

**Project Mode**

The Vivado Design Suite lets you create a project file (.xpr) and directory structure that allows you to:

- Manage the design source files.
- Store the results of the synthesis and implementation runs.
- Track the project status through the design flow.
Chapter 1: Preparing for Implementation

Working in Project Mode

In Project Mode, a directory structure is created on disk to help you manage design sources, run results and reports, as well as project status.

The automated management of the design data, process, and status requires a project infrastructure that is stored in the Vivado project file (.xpr).

In Project Mode, the Vivado tools automatically write checkpoint files into the local project directory at key points in the design flow.

Running implementation in Project Mode simply involves launching the implementation run, by clicking the Run Implementation button in the IDE or by using the `launch_runs` Tcl command. See the *Vivado Design Suite User Guide: Design Flows Overview* (UG 892) [Ref 1] for more information about using projects in Vivado.

Flow Navigator

The complete design flow is integrated in the Vivado Integrated Design Environment (IDE). The Vivado IDE includes a standardized interface called the Flow Navigator.

The Flow Navigator appears in the left pane of the Vivado Design Suite main window. From the Flow Navigator you can assemble, implement, and validate the design and IP. It features a push-button interface to the entire implementation process to simplify the design flow. The figure below shows the implementation section of the Flow Navigator.

![Flow Navigator, Implementation Section](image)

*Figure 1-2: Flow Navigator, Implementation Section*
IMPORTANT: This guide does not give a detailed explanation of the Vivado IDE, except as it applies to implementation. For more information about the Vivado IDE as it relates to the entire FPGA design flow, see the Vivado Design Suite User Guide: Using the Vivado IDE (UG893) [Ref 3].

Non-Project Mode

The Vivado tools also let you work with the design in memory, without the need for a project file and local directory. Working without a project file in the compilation style flow is called Non-Project Mode. Source files and design constraints are read into memory from their current locations. The in-memory design is stepped through the design flow without being written to intermediate files.

In Non-Project Mode, you must run each design step individually, with the appropriate options for each implementation Tcl command.

Non-Project Mode allows you to apply design changes and proceed through the design flow without needing to save changes and rerun steps. You can run reports and save design checkpoints (.dcp) at any stage of the design flow.

IMPORTANT: In Non-Project Mode, when you exit the Vivado design tools, the in-memory design is lost. For this reason, Xilinx recommends that you write design checkpoints after major steps such as synthesis, placement, and routing.

You can save design checkpoints in both Project Mode and Non-Project Mode. You can only open design checkpoints in Non-Project Mode.

Similarities and Differences Between Project Mode and Non-Project Mode

Vivado implementation can be run in either Project Mode or Non-Project Mode. The Vivado IDE and Tcl API can be used in both Project Mode and Non-Project Mode.

There are many differences between Project Mode and Non-Project Mode. Features not available in Non-Project Mode include:

• Flow Navigator
• Design status indicators
• IP catalog
• Implementation runs and run strategies
• Design Runs window
• Messages window
• Reports window

Note: This list illustrates features that are not supported in Non-Project Mode. It is not exhaustive.
You must implement the non-project based design by running the individual Tcl commands:

- `opt_design`
- `power_opt_design` (optional)
- `place_design`
- `phys_opt_design` (optional)
- `route_design`
- `write_bitstream`

You can run implementation steps interactively in the Tcl Console, in the Vivado IDE, or by using a custom Tcl script. You can customize the design flow as needed to include reporting commands and additional optimizations. For more information, see Running Implementation in Non-Project Mode.

The details of running implementation in Project Mode and Non-Project Mode are described in this guide.

For more information on running the Vivado Design Suite using either Project Mode or Non-Project Mode, see:

- *Vivado Design Suite User Guide: Using the Vivado IDE (UG893)* [Ref 3]

**Beginning the Implementation Flow**

The implementation flow typically begins by loading a synthesized design into memory. Then the implementation flow can run, or the design can be analyzed and refined along with its constraints and the design can be reloaded after updates.

There are two ways to begin the implementation flow with a synthesized design:

- Run Vivado synthesis. In Project Mode, the synthesis run contains the synthesis results and those results are automatically used as the input for implementation run. In Non-Project Mode, the synthesis results are in memory after `synth_design` completes, and implementation can continue from that point.
- Load a synthesized netlist. Synthesized netlists can be used as the input design source, for example when using a third-party tool for synthesis.

To initiate implementation:

- In Project Mode, launch the implementation run.
- In Non-Project Mode run a script or interactive commands.
To analyze and refine constraints, the synthesized design is loaded without running implementation.

- In Project Mode, you accomplish this by opening the Synthesized Design, which is the result of the synthesis run.
- In Non-Project Mode, you use the `link_design` command to load the design.

You can also drive the implementation flow using design checkpoints in Non-Project Mode. Opening a checkpoint loads the design and restores it to its original state, which might include placement and routing data. This enables re-entrant implementation flows, such as loading a routed design and editing the routing, or loading a placed design and running multiple routes with different options.

**Importing Previously Synthesized Netlists**

The Vivado Design Suite supports netlist-driven design by importing previously synthesized netlists from Xilinx or third-party tools. The netlist input formats include:

- Structural Verilog
- Structural SystemVerilog
- EDIF
- Xilinx NGC
- Synthesized Design Checkpoint (DCP)

**IMPORTANT:** When using IP in Project Mode or Non-Project Mode, always use the XCI file not the DCP file. This ensures that IP output products are used consistently during all stages of the design flow. If the IP was synthesized out-of-context and already has an associated DCP file, the DCP file is automatically used and the IP is not re-synthesized. For more information, see the Vivado Design Suite User Guide: Designing with IP (UG896) [Ref 4].

For more information on the source files and project types supported by the Vivado Design Suite, see the Vivado Design Suite User Guide: System-Level Design Entry (UG895) [Ref 6].

**Starting From RTL Sources**

At a minimum, Vivado implementation requires a synthesized netlist. A design can start from a synthesized netlist, or from RTL source files.

**IMPORTANT:** If you start from RTL sources, you must first run Vivado synthesis before implementation can begin. The Vivado IDE manages this automatically if you attempt to run implementation on an un-synthesized design. The tools allow you to run synthesis first.

For information on running Vivado synthesis, see the Vivado Design Suite User Guide: Synthesis (UG901) [Ref 8].
Creating and Opening the Synthesized Design in Non-Project Mode

In Non-Project Mode, you must run the Tcl command `synth_design` to create and open the synthesized design. You can also run the Tcl command `link_design` to open a synthesized netlist in any supported input format. You can open a synthesized design checkpoint file using the `open_checkpoint` command.

For more information, see Opening the Synthesized Design in Chapter 2, Implementing the Design.

Loading the Design Netlist in Project Mode Before Implementation

In Project Mode, after synthesis of an RTL design, or with a netlist-based project open, you can load the design netlist for analysis before implementation.

To open a synthesized design, do one of the following:

- From the main menu, run **Flow > Open Synthesized Design**.
- In the Flow Navigator, run **Synthesis > Open Synthesized Design**.
- In the Design Runs window, select the synthesis run and select **Open Synthesized Design** from the context menu.

Configuring, Implementing, and Verifying IP

For information on importing IP into your design prior to synthesis, see the Vivado Design Suite User Guide: Designing with IP (UG896) [Ref 4].

Guiding Implementation with Design Constraints

**RECOMMENDED**: Include design constraints to guide implementation. There are two types of design constraints, physical constraints and timing constraints.

There are two types of design constraints, physical constraints and timing constraints. These are defined below.
Physical Constraints Definition

Physical constraints define a relationship between logical design objects and device resources such as:

- Package pin placement
- Absolute or relative placement of cells, including:
  - Block RAM
  - DSP
  - LUT
  - Flip-flops
- Floorplanning constraints that assign cells to general regions of a device.
- Device configuration settings

Timing Constraints Definition

Timing constraints define the frequency requirements for the design, and are written in industry standard SDC.

Without timing constraints, the Vivado Design Suite optimizes the design solely for wire length and routing congestion, and makes no effort to assess or improve design performance.

UCF Format Not Supported

**IMPORTANT:** The Vivado Design Suite does not support the UCF format.

For information on migrating UCF constraints to XDC commands, see the *ISE to Vivado Design Suite Migration Guide* (UG911) [Ref 16].

Constraint Sets Apply Lists of Constraint Files to Your Design

A constraint set is a list of constraint files that can be applied to your design in Project Mode. The set contains design constraints captured in XDC files.
Chapter 1: Preparing for Implementation

Allowed Constraint Set Structures

The following constraint set structures are allowed:

- Multiple constraint files within a constraint set
- Constraint sets with separate physical and timing constraint files
- A master constraint file
- A new constraint file that accepts constraint changes
- Multiple constraint sets

**TIP:** Separate constraints by function into different constraint files to (a) make your constraint strategy clearer, and (b) to facilitate targeting timing and implementation changes.

Multiple Constraint Sets Are Allowed

You can have multiple constraint sets for a project. Multiple constraint sets allow you to use different implementation runs to test different approaches.

For example, you can have one constraint set for synthesis, and a second constraint set for implementation. Having two constraint sets allows you to experiment by applying different constraints during synthesis, simulation, and implementation.

Organizing design constraints into multiple constraint sets can help you:

- Target various Xilinx FPGA devices for the same project. Different physical and timing constraints might be needed for different target devices.
- Perform what-if design exploration. Use constraint sets to explore various scenarios for floorplanning and over-constraining the design.
- Manage constraint changes. Override master constraints with local changes in a separate constraint file.

**TIP:** To validate the timing constraints, run report_timing_summary on the synthesized design. Fix problematic constraints before implementation!

For more information on defining and working with constraints that affect placement and routing, see the Vivado Design Suite User Guide: Using Constraints (UG903) [Ref 9].

Adding Constraints as Attribute Statements

Constraints can be added to HDL sources as attribute statements. Attributes can be added to both Verilog and VHDL sources to pass through to Vivado synthesis or Vivado implementation.
In some cases, constraints are available only as HDL attributes, and are not available in XDC. In those cases, the constraint must be specified as an attribute in the HDL source file. For example, Relatively Placed Macros (RPMs) must be defined using HDL attributes. An RPM is a set of logic elements (such as FF, LUT, DSP, and RAM) with relative placements.

You can define RPMs using \texttt{U\_SET} and \texttt{HU\_SET} attributes and define relative placements using Relative Location Attributes.

For more information about Relative Location Constraints, see the \textit{Vivado Design Suite User Guide: Using Constraints} (UG903) [Ref 9].

For more information on constraints that are not supported in XDC, see the \textit{ISE to Vivado Design Suite Migration Guide} (UG911) [Ref 16].

\section*{Using Design Checkpoints to Save and Restore Snapshots}

The Vivado Design Suite uses a physical design database to store placement and routing information. Design checkpoint files (.dcp) allow you to save and restore this physical database at key points in the design flow. A checkpoint is a snapshot of a design at a specific point in the flow.

This design checkpoint file includes:

- Current netlist, including any optimizations made during implementation
- Design constraints
- Implementation results

Checkpoint designs can be run through the remainder of the design flow using Tcl commands. They cannot be modified with new design sources.

\begin{center}
\textbf{IMPORTANT: In Project Mode, the Vivado design tools automatically save and restore checkpoints as the design progresses. In Non-Project Mode, you must save checkpoints at appropriate stages of the design flow, otherwise, progress is lost.}
\end{center}

\section*{Writing Checkpoint Files}

Run \texttt{File > Write Checkpoint} to capture a snapshot of the design database at any point in the flow. This creates a file with a .dcp extension.

The related Tcl command is \texttt{write_checkpoint}.
Chapter 1: Preparing for Implementation

Reading Checkpoint Files

Run File > Open Checkpoint to open the checkpoint in the Vivado Design Suite.

The design checkpoint is opened as a separate project.

The related Tcl command is open_checkpoint.
Implementing the Design

Running Implementation in Non-Project Mode

To implement the synthesized design or netlist onto the targeted Xilinx® FPGA devices in Non-Project Mode, you must run the Tcl commands corresponding to the Implementation sub-processes:

- Opt Design: Optimizes the logical design to make it easier to fit onto the target Xilinx device.
- Power Opt Design (optional): Optimizes design elements to reduce the power demands of the target Xilinx device.
- Place Design: Places the design onto the target Xilinx device.
- Post-Place Power Opt Design (optional): Additional optimization to reduce power after placement.
- Post-Place Phys Opt Design (optional): Optimizes logic and placement using estimated timing based on placement. Includes replication of high fanout drivers.
- Route Design: Routes the design onto the target Xilinx device.
- Write Bitstream: Generates a bitstream for Xilinx device configuration. Typically, bitstream generation follows implementation.

For more information about writing the bitstream, see *Vivado Design Suite User Guide: Programming and Debugging* (UG908) [Ref 12].

These steps are collectively known as *implementation*.

Enter the commands in any of the following ways:

- In the Tcl Console from the Vivado® IDE.
- From the Tcl prompt in the Vivado Design Suite Tcl shell.
- Using a Tcl script with the implementation commands and source the script in the Vivado Design Suite.
Non-Project Mode Example Script

The script below is an example of running implementation in Non-Project Mode. Assuming the script is named `run.tcl`, you would call the script using the source command in the Tcl shell: `source run.tcl`.

```tcl
# Step 1: Read in top-level EDIF netlist from synthesis tool
read_edif c:/top.edf
# Read in lower level IP core netlists
read_edif c:/core1.edf
read_edif c:/core2.edf

# Step 2: Specify target device and link the netlists
# Merge lower level cores with top level into single design
link_design -part xc7k325tfbg900-1 -top top

# Step 3: Read XDC constraints to specify timing requirements
read_xdc c:/top_timing.xdc
# Read XDC constraints that specify physical constraints such as pin locations
read_xdc c:/top_physical.xdc

# Step 4: Optimize the design with default settings
opt_design

# Step 5: Place the design and save a checkpoint
# It is recommended to save progress at certain intermediate steps
# The placed checkpoint can also be routed in multiple runs using different options
place_design
write_checkpoint post_place.dcp

# Step 6: Route the design
route_design

# Step 7: Run Timing Summary Report to see timing results
report_timing_summary -file post_route_timing.rpt
# Run Utilization Report for device resource utilization
report_utilization -file post_route_utilization.rpt

# Step 8: Write checkpoint to capture the design database;
# The checkpoint can be used for design analysis in Vivado IDE or TCL API
write_checkpoint post_route.dcp
```
Key Steps in Non-Project Mode Example Script

The key steps in the Non-Project Mode Example Script, page 19 above, are:

- Step 1: Read Design Source Files
- Step 2: Build the In-Memory Design
- Step 3: Read Design Constraints
- Step 4: Perform Logic Optimization
- Step 5: Place the Design
- Step 6: Route the Design
- Step 7: Run Required Reports
- Step 8: Save the Design Checkpoint

**Step 1: Read Design Source Files**

EDIF netlist design sources are read into memory through use of the read_edif command. Non-Project Mode also supports an RTL design flow, which allows you to read source files and run synthesis before implementation.

Use the read_checkpoint command to add synthesized design checkpoint files as sources.

The read_* Tcl commands are designed for use with Non-Project Mode. The read_* Tcl commands allow the Vivado tools to read a file on the disk and build the in-memory design without copying the file or creating a dependency on the file.

This approach makes Non-Project Mode highly flexible with regard to design.

**IMPORTANT:** You must monitor any changes to the source design files, and update the design as needed.

**Step 2: Build the In-Memory Design**

The Vivado tools build an in-memory view of the design using link_design. The link_design command combines the netlist based source files read into the tools with the Xilinx part information, to create a design database in memory.

All actions taken in Non-Project Mode are directed at the in-memory database within the Vivado tools.

The in-memory design resides in the Vivado tools, whether running in batch mode, Tcl shell mode for interactive Tcl commands, or in the Vivado IDE for interaction with the design data in a graphical form.
**Step 3: Read Design Constraints**

The Vivado Design Suite uses design constraints to define requirements for both the physical and timing characteristics of the design.

For more information, see Guiding Implementation with Design Constraints, page 13.

The `read_xdc` command reads an XDC constraint file, then applies it to the in-memory design.

**TIP:** Although Project Mode supports the definition of constraint sets, containing multiple constraint files for different purposes, Non-Project Mode uses multiple `read_xdc` commands to achieve the same effect.

**Step 4: Perform Logic Optimization**

Logic optimization is run in preparation for placement and routing. Optimization simplifies the logic design before committing to physical resources on the target part.

The Vivado netlist optimizer includes many different types of optimizations to meet varying design requirements. For more information, see Logic Optimization, page 50.

**Step 5: Place the Design**

The `place_design` command places the design. For more information, see Placement, page 57. After placement, the progress is saved to a design checkpoint file using the `write_checkpoint` command.

**Step 6: Route the Design**

The `route_design` command routes the design. For more information, see Routing, page 72.

**Step 7: Run Required Reports**

The `report_timing_summary` command runs timing analysis and generates a timing report with details of timing violations. The `report_utilization` command generates a summary of the percentage of device resources used along with other utilization statistics. In Non-Project Mode, you must use the appropriate Tcl command to specify each report that you want to create. Each reporting command supports the `-file` option to direct output to a file. See the Vivado Design Suite Tcl Command Reference Guide (UG835) [Ref 15] for further information on reporting commands.

You can output reports to files for later review, or you can send the reports directly to the Vivado IDE to review now. For more information, see Viewing Implementation Reports, page 103.
**Step 8: Save the Design Checkpoint**

Saves the in-memory design into a design checkpoint file. The saved in-memory design includes its:

- Logical netlist
- Physical and timing related constraints
- Xilinx part data
- Placement and routing information

In Non-Project Mode, the design checkpoint file saves the design and allows it to be reloaded for further analysis and modification.

For more information, see *Using Design Checkpoints to Save and Restore Snapshots*, page 16.

---

**Running Implementation in Project Mode**

In Project Mode, the Vivado IDE allows you to:

- Define implementation runs that are configured to use specific synthesis results and design constraints.
- Run multiple strategies on a single design.
- Customize implementation strategies to meet specific design requirements.
- Save customized implementation strategies to use in other designs.

**IMPORTANT:** Non-Project Mode does not support predefined implementation runs and strategies. Non-project based designs must be manually moved through each step of the implementation process using Tcl commands. For more information, see *Running Implementation in Non-Project Mode*, page 18.

---

**Creating Implementation Runs**

You can create and launch new implementation runs to explore design alternatives and find the best results. You can queue and launch the runs serially or in parallel using multiple, local CPUs.

On Linux systems, you can launch runs on remote servers. For more information, see *Appendix A, Using Remote Hosts and LSF.*
Defining Implementation Runs

To define an implementation run:

1. From the main menu, select Flow > Create Runs.

   (Alternatively: in the Flow Navigator, select Create Implementation Runs from the Implementation popup menu. Or, in the Design Runs window, select Create Runs from the popup menu.)

   The Create New Runs wizard opens.

2. Select Implementation on the first page of the Create New Runs wizard, and click Next.

3. The Configure Implementation Runs screen appears, as shown in the figure below. Specify settings as described in the steps below the figure.

![Configure Implementation Runs](image)

**Figure 2-1: Configure Implementation Runs**

a. In the Name column, enter a name for the run in the Configure Implementation Runs dialog box or accept the default name.

b. Select a Synth Name to choose the synthesis run that will generate (or that has already generated) the synthesized netlist to be implemented. In the case of a Netlist driven project, the Create Run command does not require the name of the synthesis run.

   Alternatively, you can select a synthesized netlist that was imported into the project from a third-party synthesis tool.

   For more information, see the Vivado Design Suite User Guide: Synthesis (UG901) [Ref 8].
Chapter 2: Implementing the Design

The default is the currently active synthesis run in the Design Runs window. For more information, see Appendix C, Implementation Categories, Strategy Descriptions, and Directive Mapping.

c. Select a **Constraints Set** to apply during implementation. The optimization, placement, and routing are largely directed by the physical and timing constraints in the specified constraint set.

For more information on constraint sets, see the *Vivado Design Suite User Guide: Using Constraints* (UG903) [Ref 9].

d. Select a target **Part**.

The default values for Constraints Set and Part are defined by the Project Settings when the **Create New Runs** command is executed.

For more information on the Project Settings, see the *Vivado Design Suite User Guide: Using the Vivado IDE* (UG893) [Ref 3].

**TIP:** To create runs with different constraint sets or target parts, use the **Create New Runs** command. To change these values on existing runs, select the run in the **Design Runs** window and edit the Run Properties.

For more information, see Changing Implementation Run Settings, page 28.

e. Select a **Strategy**.

Strategies are a defined set of Vivado implementation feature options that control the implementation results. Vivado Design Suite includes a set of pre-defined strategies. You can also create your own implementation strategies.

Select from among the strategies shown in Appendix C, Implementation Categories, Strategy Descriptions, and Directive Mapping.

The strategies are broken into categories according to their purposes, with the category name as a prefix. The categories are shown in Appendix C, Implementation Categories, Strategy Descriptions, and Directive Mapping.

For more information see Defining Strategies, page 35.

The purpose of using Performance strategies is to improve design performance at the expense of run time. You should always try to meet timing goals, using the Vivado implementation defaults first, before choosing a Performance strategy. This ensures that your design has sufficient margin for absorbing timing closure impact due to design changes. But if your design goals cannot be met, and if increased run time is acceptable, the **PerformanceExplore** strategy is a good first choice. It covers all types design types.
Chapter 2: Implementing the Design

**IMPORTANT:** Strategies containing the terms SLL or SLR are for use with SSI devices only.

**TIP:** Before launching a run, you can change the settings for each step in the implementation process, overriding the default settings for the selected strategy. You can also save those new settings as a new strategy. For more information, see Changing Implementation Run Settings, page 28.

f. Click **More** to define additional runs. By default, the next strategy in the sequence is automatically chosen. Specify names and strategies for the added runs. See Figure 2-1, above.

g. Use the **Make Active** check box to select the runs you wish to initiate.

h. Click **Next**.

4. The Launch Options screen appears, as shown in the figure below. Specify options as described in the steps below the figure.

![Implementation Launch Options](image)

**Figure 2-2:** Implementation Launch Options

**Note:** The **Launch runs on remote hosts** option shown in the figure above is Linux-only. It is not visible on Windows machines.

a. Specify the Launch directory, the location at which implementation run data is created and stored.

The default directory is located in the local project directory structure. Files for implementation runs are stored by default at:

```
<project_name>/<project_name>.runs/<run_name>
```
b. Use the radio buttons and drop down options to specify settings appropriate to your project. Choose from the following:

- Select the **Launch runs on local host** option if you want to launch the run on the local machine.

- Use the **Number of jobs** drop-down menu to define the number of local processors to use when launching multiple runs simultaneously.

- Select **Launch runs on remote hosts** (Linux only) if you want to use remote hosts to launch one or more jobs.

- Use the **Configure Hosts** button to configure remote hosts. For more information, see Appendix A, Using Remote Hosts and LSF.

- Select **Launch runs using LSF** (Linux only) if you want to use LSF (Load Sharing Facility) `bsub` command to launch one or more jobs. Use the **Configure LSF** button to set up the `bsub` command options and test your LSF connection.

**TIP:** *Defining a directory location outside the project directory structure makes the project non-portable, because absolute paths are written into the project files.*

- Select the **Generate scripts only** option if you want to export and create the run directory and run script but do not want the run script to launch at this time. The script can be run later outside the Vivado IDE tools.

- Select **do not launch now** if you want to save the new runs, but you do *not* want to launch or create run scripts at this time.

5. Click **Next** to review the Create New Runs Summary.

6. Click **Finish** to create the defined runs and execute the specified launch options.

New runs are added to the Design Runs window. See Using the Design Runs Window.

**Using the Design Runs Window**

The Design Runs window displays all synthesis and implementation runs created in the project. It includes commands to configure, manage, and launch the runs.

**Opening the Design Runs Window**

Select **Window > Design Runs** to open the Design Runs window (see the figure below) if it is not already open.
Design Runs Window Functionality

- Each implementation run appears indented beneath the synthesis run of which it is a child.
- A synthesis run can have multiple implementation runs. Use the tree widgets in the window to expand and collapse synthesis runs.
- The Design Runs window is a tree table window.

For more information on working with the columns to sort the data in this window, see the Vivado Design Suite User Guide: Using the Vivado IDE (UG893) [Ref 3].

Run Status

The Design Runs window reports the run status, including when:

- The run has not been started.
- The run is in progress.
- The run is complete.
- The run is out-of-date.

The Design Runs window reports start and elapsed run times.

Run Times

The Design Runs window reports start time and elapsed time for the runs.

Run Timing Results

The Design Runs window reports timing results for implementation runs including WNS, TNS, WHS, THS, and TPWS.
Chapter 2: Implementing the Design

Out-of-Date Runs

Runs can become out-of-date when source files, constraints, or project settings are modified. You can reset and delete stale run data in the Design Runs window.

Active Run

All views in the Vivado IDE reference the active run. The Log view, Report view, Status Bar, and Project Summary display information for the active run. The Project Summary window displays only compilation, resource, and summary information for the active run.

TIP: Only one synthesis run and one implementation run can be active in the Vivado IDE at any time.

The active run is displayed in bold text.

To make a run active:

1. Select the run in the Design Runs window.
2. Select Make Active from the popup menu.

Changing Implementation Run Settings

Select a run in the Design Runs window to display the current configuration of the run in the Run Properties window, shown in Figure 2-4, below.

In the Run Properties window you can change:

- The name of the run
- The Xilinx part targeted by the run
- The run description
- The constraints set that both drives the implementation and is the target of new constraints from implementation

For more information on the Run Properties window, see the Vivado Design Suite User Guide: Using the Vivado IDE (UG893) [Ref 3].
Chapter 2: Implementing the Design

Specifying Design Run Settings

Specify design run settings in the Design Run Settings dialog box, shown in the figure below. To open the Design Run Settings dialog box:

1. Right-click a run in the Design Runs window.
2. Select Change Run Settings from the popup menu to open the Design Run Settings dialog box, shown in the figure below.

TIP: You can change the settings only for a run that has a Not Started status. Use Reset Run to return a run to the Not Started status. See Resetting Runs, page 32.
Chapter 2: Implementing the Design

The Design Run Settings dialog box displays: (1) the implementation strategy currently employed by the run; and (2) the command options associated with that strategy for each step of the implementation process. The three command options are described below.

**Strategy**

Selects the strategy to use for the implementation run. Vivado Design Suite includes a set of pre-defined implementation strategies, or you can create your own.

For more information see Defining Strategies, page 35.

**Description**

Describes the selected implementation strategy.

**Options**

When you select a strategy, each step of the Vivado implementation process displays in a table in the lower part of the dialog box:

- Opt Design (opt_design)
- Power Opt Design (power_opt_design) *(optional)*
- Place Design (place_design)
Chapter 2: Implementing the Design

- Post-Place Power Opt Design (power_opt_design) *(optional)*
- Post-Place Phys Opt Design (phys_opt_design) *(optional)*
- Route Design (route_design)
- Post-Route Phys Opt Design (phys_opt_design) *(optional)*
- Write Bitstream (write_bitstream)

Click the command option to view a brief description of the option at the bottom of the Design Run Settings dialog box.

For more information about the implementation steps and their available options, see Chapter 2, Implementing the Design.

**Modifying Command Options**

To modify command options, click the right-side column of a specific option. You can do the following:

- Select options with predefined settings from the pull down menu.
- Select or deselect a check box to enable or disable options.

**Note:** The most common options for each implementation command are available through the check boxes. Add other supported command options using the More Options field. Syntax: precede option names with a hyphen and separate options from each other with a space.

- Type a value to define options that accept a user-defined value.
- Options accepting a file name and path open a file browser to let you locate and specify the file.
- Insert a custom Tcl script (called a hook script) before and after each step in the implementation process (tcl.pre and tcl.post).

Inserting a hook script lets you perform specific tasks before or after each implementation step (for example: generate a timing report before and after Place Design to compare timing results).

For more information on defining Tcl hook scripts, see the *Vivado Design Suite User Guide: Using Tcl Scripting (UG894)* [Ref 5].

**TIP:** Relative paths in the tcl.pre and tcl.post scripts are relative to the appropriate run directory of the project they are applied to: `<project>/<project.runs>/<run_name>`

Use the DIRECTORY property of the current project or current run to define the relative paths in your Tcl scripts:

```
get_property DIRECTORY [current_project]
get_property DIRECTORY [current_run]
```
**Save Strategy As**

Select the **Save Strategy As** icon next to the Strategy field to save any changes to the strategy as a new strategy for future use.

**CAUTION!** If you do not select **Save Strategy As**, changes are saved to the current implementation run, but are not preserved for future use.

**Verifying Run Status**

The Vivado IDE processes the run and launches implementation, depending on the status of the run. The status is displayed in the Design Runs window (shown in Figure 2-3).

- If the status of the run is **Not Started**, the run begins immediately.
- If the status of the run is **Error**, the tools reset the run to remove any incomplete run data, then restarts the run.
- If the status of the run is **Complete** (or **Out-of-Date**), the tools prompt you to confirm that the run should be reset before proceeding with the run.

**Resetting Runs**

To reset a run:

1. Select a run in the Design Runs window.
2. Select **Reset Runs** from the popup menu.

Resetting an implementation run returns it to the first step of implementation (opt_design) for the selected run.

As shown in the figure below, the Vivado tools prompt you to confirm the **Reset Runs** command, and optionally delete the generated files from the run directory.
**TIP:** The default setting is to delete the generated files. Disable this check box to preserve the generated run files.

**Deleting Runs**

To delete runs from the Design Runs window:

1. Select the run.
2. Select **Delete** from the popup menu.

As shown in the figure below, the Vivado tools prompt you to confirm the **Delete Runs** command, and optionally delete the generated files from the run directory.

**TIP:** The default setting is to delete the generated files. Disable this check box to preserve the generated run files.

![Delete Runs Prompt](image)

**Figure 2-7:** Delete Runs Prompt

---

**Customizing Implementation Strategies**

Implementation Settings define the default options used when you define new implementation runs. Configure these options in the Vivado IDE.

**Figure 2-8** shows the Implementation Settings view in the Project Settings dialog box. To open this dialog box from the Vivado IDE, select **Tools > Project Settings** from the main menu.

**TIP:** The Project Settings command is not available in the Vivado IDE when running in Non-Project Mode. In this case, you can define and preserve implementation strategies as Tcl scripts that can be used in batch mode, or interactively in the Vivado IDE.
Accessing Implementation Settings for the Active Run from Flow Navigator

Implementation Settings for the active implementation run can also be accessed directly from the Flow Navigator.

The Implementation Settings dialog box, shown in Figure 2-8, contains the following fields:

- Default Constraint Set:
  Select the constraint set to be used by default for the implementation run.

- Incremental Compile:
  Specify the Incremental Compile checkpoint, if desired.

- Strategy:
  Select the strategy to use for the implementation run. The Vivado Design Suite includes a set of pre-defined strategies. You can also create your own implementation strategies and save changes as new strategies for future use. For more information see Defining Strategies.

- Description:
  Describes the selected implementation strategy. The description of user-defined
strategies can be changed by entering a new descriptions. The description of Vivado tools standard implementation strategies cannot be changed.

![Implementation Settings](image)

**Figure 2-8: Implementation Settings**

### Defining Strategies

A strategy is a defined approach for resolving the synthesis or implementation challenges of the design.

- Strategies are defined in pre-configured sets of options for the Vivado implementation features.
- Strategies are tool and version specific.
- Each major release of the Vivado Design Suite includes version-specific strategies.
Vivado implementation includes several commonly used strategies that are tested against internal benchmarks.

**TIP:** You cannot save changes to the predefined implementation strategies. However, you can copy, modify, and save the predefined strategies to create your own.
Accessing Currently Defined Strategies

To access the currently defined strategies, select **Tools > Options** in the Vivado IDE main menu.

Reviewing,Copying, and Modifying Strategies

To review, copy, and modify strategies:

1. Select **Tools > Options** from the main menu.
2. Select **Strategies** in the left-side panel.

   The Strategies dialog box (shown in Figure 2-9, above) contains a list of pre-defined strategies for various tools and release versions.

3. In the **Flow** pull-down menu, select the appropriate **Vivado Implementation** version for the available strategies. A list of included strategies is displayed.

4. To create a new strategy, select **Create New Strategy** on the toolbar or from the popup menu.

5. To copy an existing strategy, select **Create a copy of this strategy** from the toolbar or from the popup menu. The Vivado design tools:
   a. Create a copy of the currently selected strategy.
   b. Add it to the User Defined Strategies list.
   c. Display the strategy options on the right side of the dialog box for you to modify.

6. Provide a name and description for the new strategy as follows:
   - **Name**
     Enter a strategy name to assign to a run.
   - **Type**
     Specify Synthesis or Implement.
   - **Tool Version**
     Specify the tool version.
   - **Description**
     Enter the strategy description displayed in the Design Run results table.

7. Edit the **Options** for the various implementation steps:
   - **Opt Design** (opt_design)
   - **Power Opt Design** (power_opt_design) (optional)
   - **Place Design** (place_design)
   - **Post-Place Power Opt Design** (power_opt_design) (optional)
Chapter 2: Implementing the Design

- Post-Place Phys Opt Design (phys_opt_design) (optional)
- Route Design (route_design)
- Post-Route Phys Opt Design (phys_opt_design) (optional)
- Write Bitstream (write_bitstream)

**TIP:** Select an option to view a brief description of the option at the bottom of the Design Run Settings dialog box.

For more information about the implementation steps and their options, see Chapter 2, Implementing the Design.

---

**Place Design (place_design)**

<td></td>
</tr>
</tbody>
</table>

---

**Figure 2-10: Edit Implementation Steps**

8. Click the right-side column of a specific option to modify command options. See Figure 2-10, Edit Implementation Steps, immediately above for an example.

You can then:

- Select predefined options from the pull down menu.
- Enable or disable some options with a check box.
- Type a user-defined value for options with a text entry field.
- Use the file browser to specify a file for options accepting a file name and path.
- Insert a custom Tcl script (called a hook script) before and after each step in the implementation process (tcl.pre and tcl.post). This lets you perform specific tasks either before or after each implementation step (for example, generating a timing report before and after Place Design to compare timing results).

For more information on defining Tcl hook scripts, see the Vivado Design Suite User Guide: Using Tcl Scripting (UG894) [Ref 5].
Note: Relative paths in the tcl.pre and tcl.post scripts are relative to the appropriate run directory of the project they are applied to: 
<project>/<project.runs>/<run_name>

You can use the DIRECTORY property of the current project or current run to define the relative paths in your scripts:

get_property DIRECTORY [current_project]
get_property DIRECTORY [current_run]

9. Click OK to save the new strategy.

The new strategy is listed under User Defined Strategy. The Vivado tools save user-defined strategies to the following locations:

- **Linux OS**
  
  $HOME/.Xilinx/Vivado/strategies

- **Windows 7**
  
  C:\Users\<username>\AppData\Roaming\Xilinx\Vivado\strategies

- **Windows XP**
  
  C:\Documents and Settings\<username>\Application Data\Xilinx\Vivado\strategies

### Sharing Strategies

Design teams that want to create and share strategies can copy any user-defined strategy from the user directory to the <InstallDir>/Vivado/<version>/strategies directory

where

- `<InstallDir>` is the installation directory of the Xilinx software.
- `<version>` is the release version.
Chapter 2: Implementing the Design

Launching Implementation Runs

Do any of the following to launch the active implementation run in the Design Runs window:

- Select Run Implementation in the Flow Navigator.
- Select Flow > Run Implementation from the main menu.
- Select Run Implementation from the toolbar menu.
- Select a run in the Design Runs window and select Launch Runs from the popup menu.

Launching a single implementation run initiates a separate process for the implementation.

**TIP:** Select a run in the Design Runs window to launch a run other than the active run. Select two or more runs in the Design Runs window to launch multiple runs at the same time.

1. Use **Shift+click** or **Ctrl+click** to select multiple runs.

   **Note:** You can choose both synthesis and implementation runs when selecting multiple runs in the Design Runs window. The Vivado IDE manages run dependencies and launches runs in the correct order.

2. Select **Launch Runs** to open the Launch Selected Runs dialog box, shown in the figure below.

   **Note:** You can select **Launch Runs** from the popup menu, or from the Design Runs window toolbar menu.
3. Select **Launch Directory**.

The default launch directory is in the local project directory structure. Files for implementation runs are stored at:

<project_name>/<project_name>.runs/<run_name>

**TIP:** Defining any non-default location outside the project directory structure makes the project non-portable because absolute paths are written into the project files.

4. Specify Options.

- Select the **Launch runs on local host** option if you want to launch the run on the local machine.

- Use the **Number of jobs** drop-down menu to define the number of local processors to use when launching multiple runs simultaneously.

- Select **Launch runs on remote hosts** (Linux only) if you want to use remote hosts to launch one or more jobs.

- Use the **Configure Hosts** button to configure remote hosts. For more information, see Appendix A, Using Remote Hosts and LSF.

- Select **Launch runs using LSF** (Linux only) if you want to use LSF (Load Sharing Facility) `bsub` command to launch one or more jobs. Use the **Configure LSF** button to set up the `bsub` command options and test your LSF connection.
TIP: LSF, the Load Sharing Facility, is a subsystem for submitting, scheduling, executing, monitoring, and controlling a workload of batch jobs across compute servers in a cluster.

- Select the **Generate scripts only** option if you want to export and create the run directory and run script but do not launch the run script to launch at this time. The script can be run later outside the Vivado IDE tools.

- Select **do not launch now** if you want to save the new runs, but you do not want to launch or create run scripts at this time.

---

**Moving Processes to the Background**

As the Vivado IDE initiates the process to run synthesis or implementation, it reads design files and constraint files in preparation for the run. The Starting Run dialog box, shown in Figure 2-12, lets you move this preparation to the background.

Putting this process into the background releases the Vivado IDE to perform other functions while it completes the background task. The other functions can include functions such as viewing reports and opening design files. You can use this time, for example, to review previous runs, or to examine reports.

**CAUTION!** When you put this process into the background, the Tcl Console is blocked. You cannot execute Tcl commands, or perform tasks that require Tcl commands, such as switching to another open design.

---

![Figure 2-12: Start Run - Background Process](image)
Running Implementation in Steps

Vivado implementation consists of a number of smaller processes such as:

- Logic optimizer
- Placer
- Router

The Vivado tools let you run implementation as a series of steps, rather than as a single process.

How to Run Implementation in Steps

To run implementation in steps:

1. Select a run in the Design Runs window.
2. Select Launch Next Step: <Step> or Launch Step To from the popup menu.

Valid <Step> values depend on which run steps have been enabled in the Run Settings. The steps that are available in an implementation run are:

- Opt Design: Optimizes the logical design and fit sit onto the target Xilinx FPGA device.
- Power Opt Design: Optimizes elements of the design to reduce power demands of the implemented FPGA device.
- Place Design: Places the design onto the target Xilinx device.
- Post-Place Power Opt Design: Additional optimization to reduce power after placement.
- Post-Place Phys Opt Design: Performs timing-driven optimization on the negative-slack paths of a design.
- Route Design: Routes the design onto the target Xilinx device.
- Post-Route Phys Opt Design: Optimizes logic, placement, and routing, using actual routed delays.
- Write Bitstream: Generates a bitstream for Xilinx device configuration. Although not technically part of an implementation run, bitstream generation is available as an incremental step.
3. Repeat Launch Next Step: <Step> or Launch Step To as needed to move the design through implementation.

You can run any reports or analysis needed between implementation steps to explore design options.

4. To back up from a completed step, select Reset to Previous Step: <Step> from the Design Runs window popup menu.

Select Reset to Previous Step to reset the selected run from its current state to the prior incremental step. This allows you to:

- Step backward through a run.
- Make any needed changes.
- Step forward again to incrementally complete the run.

---

### About Implementation Commands

The Xilinx® Vivado® Design Suite includes many features to manage and simplify the implementation process for project-based designs. These features include the ability to step manually through the implementation process.

For more information, see Running Implementation in Project Mode, page 22.

Non-Project based designs must be manually taken through each step of the implementation process using Tcl commands or Tcl scripts.

**Note:** For more information about Tcl commands, see the Vivado Design Suite Tcl Command Reference Guide (UG835) [Ref 15], or type <command> -help.

For more information, see Running Implementation in Non-Project Mode, page 18.

---

### Implementation Sub-Processes

In Project Mode, the implementation commands are run in a fixed order. In Non-Project Mode the commands can be run in a similar order, but can also be run repeatedly, iteratively, and in a different sequence than in Project Mode.
**IMPORTANT:** *Implementation Commands are re-entrant*

Implementation commands are re-entrant, which means that when an implementation command is called in Non-Project Mode, it reads the design in memory, performs its tasks, and writes the resulting design back into memory. This provides more flexibility when running in Non-Project Mode. Examples:

- `opt_design` followed by `opt_design -remap`
  The Remap operation occurs on the `opt_design` results.

- `place_design` called on a design that contains some placed cells
  The existing cell placement is used as a starting point for `place_design`.

- `route_design` called on a design that contains some routing
  The existing routing is used as a starting point for `route_design`.

- `route_design` called on a design with unplaced cells
  Routing fails because cells must be placed first.

- `opt_design` called on a fully-placed and routed design
  Logic optimization might optimize the logical netlist, creating new cells that are unplaced, and new nets that are unrouted. Placement and routing might need to be rerun to finish implementation.

Putting a design through the Vivado implementation process, whether in Project Mode or Non-Project Mode, consists of several sub-processes:

- **Open Synthesized Design**
  Combines the netlist, the design constraints, and Xilinx target part data, to build the in-memory design to drive implementation.

- **Opt Design**
  Optimizes the logical design to make it easier to fit onto the target Xilinx device.

- **Power Opt Design (optional)**
  Optimizes design elements to reduce the power demands of the target Xilinx device.

- **Place Design**
  Places the design onto the target Xilinx device.

- **Post-Place Power Opt Design (optional)**
  Additional optimization to reduce power after placement.

- **Post-Place Phys Opt Design (optional)**
  Optimizes logic and placement using estimated timing based on placement. Includes replication of high fanout drivers.

- **Route Design**
  Routes the design onto the target Xilinx device.

- **Post-Route Phys Opt Design**
  Optimizes logic, placement, and routing using actual routed delays (optional).
• **Write Bitstream**
  Generates a bitstream for Xilinx device configuration.

  *Note:* Although not technically part of an implementation run, Write Bitstream is available as a separate step.

To provide a better understanding of the individual steps in the implementation process, the details of each step, and the associated Tcl commands, are documented in this chapter.

The table below provides a list of sub-processes and their associated Tcl commands.

**Table 2-1: Implementation Sub-processes and Associated Tcl Commands**

For a complete description of the Tcl reporting commands and their options, see the *Vivado Design Suite Tcl Command Reference Guide* (UG835) [Ref 15].

---

**Opening the Synthesized Design**

The first steps in implementation are to read the netlist from the synthesized design into memory and apply design constraints. You can open the synthesized design in various ways, depending on the flow used.

**Creating the In-Memory Design**

To create the in-memory design, the Vivado Design Suite uses the following process to combine the netlist files, constraint files, and the target part information:

1. **Assembles the netlist.**

   The netlist is assembled from multiple sources if needed. Designs can consist of a mix of structural Verilog, EDIF, and NGC.
2. Transforms legacy netlist primitives to the currently supported subset of Unisim primitives.

**TIP:** Use `report_transformed_primitives` to generate a list of transformed cells.

3. Processes constraints from XDC files.

   These constraints include both timing constraints and physical constraints such as package pin assignments and Pblocks for floorplanning.

   **IMPORTANT:** Review critical warnings that identify failed constraints. Constraints might be placed on design objects that have been optimized or no longer exist. The Tcl command `write_xdc -constraints INVALID` also captures invalid XDC constraints.

   The Vivado tools create placement macros of cells, based on their connectivity or placement constraints to simplify placement.

   Examples of placement macros include:

   - An XDC-based macro.
   - A relatively placed macro (RPM).
     **Note:** RPMs are placed as a group rather than as individual cells.
   - A long carry chain that needs to be placed in multiple CLBs.
     **Note:** The primitives making up the carry chains must belong to a single macro to ensure that downstream placement aligns it into vertical slices.

**Tcl Commands**

The Tcl commands shown in the table below can be used to read the synthesized design into memory, depending on the source files in the design, and the state of the design.

**Table 2-2: Modes in Which Tcl Commands Can Be Used**

<table>
<thead>
<tr>
<th>Command</th>

<tr>
<td>open_run</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>link_design</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>
**synth_design**

The `synth_design` command can be used in both Project Mode and Non-Project Mode. It runs Vivado synthesis on RTL sources with the specified options, and reads the design into memory after synthesis.

\[
\text{synth_design} \quad [-\text{name <arg>}] \quad [-\text{part <arg>}] \quad [-\text{constrset <arg>}] \quad [-\text{top <arg>}] \\

**synth_design Example Script**

The following is an excerpt from the `create_bft_batch.tcl` script found in the `examples/Vivado_Tutorials` directory of the software installation.

```tcl
# Setup design sources and constraints
read_vhdl -library bftLib [ glob ./Sources/hdl/bftLib/*.vhdl ]
read_vhdl ./Sources/hdl/bft.vhdl
read_verilog  [ glob ./Sources/hdl/*.v ]
read_xdc ./Sources/bft_full.xdc
# Run synthesis, report utilization and timing estimates, write design checkpoint
synth_design -top bft -part xc7k70tfbg484-2 -flatten rebuilt
write_checkpoint -force $outputDir/post_synth
```

For more information on using the `synth_design` example script, see the *Vivado Design Suite Tutorial: Design Flows Overview* (UG888) [Ref 17] and the *Vivado Design Suite User Guide: Synthesis* (UG901) [Ref 8].

The `synth_design` example script reads VHDL and Verilog files; reads a constraint file; and synthesizes the design on the specified part. The design is opened by the Vivado tools into memory when `synth_design` completes. A design checkpoint is written after completing synthesis.

For a complete description of the Tcl commands and their options, see the *Vivado Design Suite Tcl Command Reference Guide* (UG835) [Ref 15].

**open_checkpoint**

In previous releases, the `read_checkpoint` command was used to read and initialize checkpoint designs. Beginning in version 2014.1, this function is provided by the `open_checkpoint` command. The behavior of `read_checkpoint` has been changed such that it only adds the checkpoint file to the list of source files. This is consistent with other read commands such as `read_verilog`, `read_vhdl`, and `read_xdc`. A separate `link_design` command is required to initialize the design and load it into memory when using `read_checkpoint`. 
Chapter 2: Implementing the Design

The `open_checkpoint` command opens a design checkpoint file (DCP), creates a new in-memory project and initializes a design immediately in the new project with the contents of the checkpoint. This command can be used to open a top-level design checkpoint, or the checkpoint created for an out-of-context module.

When opening a checkpoint, there is no need to create a project first. The `open_checkpoint` command reads the design data into memory, opening the design in Non-Project Mode. Refer to the Vivado Design Suite User Guide: Design Flows Overview (UG892) [Ref 17] for more information on Project Mode and Non-Project Mode.

**IMPORTANT:** In the incremental compile flow, the `read_checkpoint` command is still used to specify the reference design checkpoint.

---

open_checkpoint Syntax

```
open_checkpoint  [-part <arg>] [-quiet] [-verbose] <file>
```

open_checkpoint Example Script

```
# Read the specified design checkpoint and create an in-memory design.
open_checkpoint C:/Data/post_synth.dcp
```

The `open_checkpoint` example script opens the post synthesis design checkpoint file.

---

open_run

The `open_run` command opens a previously completed synthesis or implementation run, then loads the in-memory design of the Vivado tools.

**IMPORTANT:** The `open_run` command works in Project Mode only. Design runs are not supported in Non-Project Mode.

Use `open_run` before implementation on an RTL design in order to open a previously completed Vivado synthesis run then load the synthesized netlist into memory.

**TIP:** Because the in-memory design is updated automatically, you do not need to use `open_run after synth_design`. You need to use `open_run` only to open a previously completed synthesis run from an earlier design session.

The `open_run` command is for use with RTL designs only. To open a netlist-based design, use `link_design`.

open_run Syntax

```
open_run [-name <arg>] [-quiet] [-verbose] <run>
```
**open_run Example Script**

```tcl
# Open named design from completed synthesis run
open_run -name synth_1 synth_1
```

The open_run example script opens a design (synth_1) into the Vivado tools memory from the completed synthesis run (also named synth_1).

If you use open_run while a design is already in memory, the Vivado tools prompt you to save any changes to the current design before opening the new design.

**link_design**

The link_design command creates an in-memory design from netlist sources (such as from a third-party synthesis tool), and links the netlists and design constraints with the target part.

**TIP:** The link_design command supports both Project Mode and Non-Project Mode to create the netlist design.

**link_design Syntax**

```tcl
link_design [-name <arg>] [-part <arg>] [-constrset <arg>] [-top <arg>]
            [-mode <arg>] [-quiet] [-verbose]
```

**link_design Example Script**

```tcl
# Open named design from netlist sources.
link_design -name netDriven -constrset constrs_1 -part xc7k325tfbg900-1
```

If you use link_design while a design is already in memory, the Vivado tools prompt you to save any changes to the current design before opening the new design.

**RECOMMENDED:** After creating the in-memory synthesized design in the Vivado tools, review Errors and Critical Warnings for missing or incorrect constraints. After the design is successfully created, you can begin running analysis, generating reports, applying new constraints, or running implementation.

Immediately after opening the in-memory synthesized design, run `report_timing_summary` to check timing constraints. This ensures that the design goals are complete and reasonable. For more detailed descriptions of Tcl commands, see the *Vivado Design Suite Tcl Command Reference Guide* (UG835) [Ref 15].

**Logic Optimization**

Logic optimization ensures the most efficient logic design before attempting placement. It performs a netlist connectivity check to warn of potential design problems such as nets with
multiple drivers and un-driven inputs. Logic optimization also performs block RAM power optimization.

Often design connectivity errors are propagated to the logic optimization step where the flow fails. It is important to ensure valid connectivity using DRC Reports before running implementation.

Logic optimization skips optimization of cells and nets that have DONT_TOUCH properties set to a value of true.

The Tcl command used to run Logic Optimization is opt_design.

**Available Logic Optimizations**

The Vivado tools can perform the logic optimizations on the in-memory design, as described below.

---

**IMPORTANT:** Logic optimization can be limited to specific optimizations by choosing the corresponding command options. Only those specified optimizations are run, while all others are disabled, even those normally performed by default.

---

**Retargeting (Default)**

Retargeting replaces one cell type with another to ease optimization. Example: A MUXF7 replaced by a LUT3 can be combined with other LUTs. In addition, simple cells such as inverters are absorbed into downstream logic.

**Constant Propagation (Default)**

Constant Propagation propagates constant values through logic, which results in:

- Eliminated logic:
  Example: an AND with a constant 0 input
- Reduced logic:
  Example: A 3-input AND with a constant 1 input is reduced to a 2-input AND.
- Redundant logic:
  Example: A 2-input OR with a logic 0 input is reduced to a wire.

**Sweep (Default)**

Sweep removes cells that have no loads.
Chapter 2: Implementing the Design

Block RAM Power Optimization (Default)

Block RAM Power Optimization enables power optimization on block RAM cells including:

- Changing the WRITE_MODE on unread ports of true dual-port RAMs to NO_CHANGE.
- Applying intelligent clock gating to block RAM outputs.

Remap

Remap combines multiple LUTs into a single LUT to reduce the depth of the logic.

Resynth Area

Resynth Area performs re-synthesis in area mode to reduce the number of LUTs.

Resynth Sequential Area

Resynth Sequential Area performs re-synthesis to reduce both combinational and sequential logic. Performs a superset of the optimization of Resynth Area.

IMPORTANT: Each use of logic optimization affects the in-memory design, not the synthesized design that was originally opened.

opt_design

The opt_design command runs Logic Optimization.

opt_design Syntax

```
opt_design [-retarget] [-propconst] [-sweep] [-bram_power_opt] [-remap]
[-resynth_area] [-resynth_seq_area] [-directive <arg>] [-quiet] [-verbose]
```

opt_design Example Script

```
# Run logic optimization with block RAM Power Optimization disabled, save results in
# a checkpoint, report timing estimates
opt_design -directive NoBramPowerOpt
write_checkpoint -force $outputDir/post_opt
report_timing_summary -file $outputDir/post_opt_timing_summary.rpt
```
The opt_design example script performs logic optimization on the in-memory design, rewriting it in the process. It also writes a design checkpoint after completing optimization, and generates a timing summary report and writes the report to the specified file.

Restrict Optimization to Listed Types

Use command line options to restrict optimization to one or more of the listed types. For example, the following is another method for skipping the block RAM optimization that is run by default:

```
opt_design -retarget -propconst -sweep
```

**Using Directives**

Directives provide different modes of behavior for the opt_design command. Only one directive may be specified at a time. The directive option is incompatible with other options.

The following directives are available:

- **Explore**
  Runs multiple passes of optimization.

- **ExploreArea**
  Runs multiple passes of optimization with emphasis on reducing combinational logic.

- **AddRemap**
  Runs the default logic optimization flow and includes LUT remapping to reduce logic levels.

- **ExploreSequentialArea**
  Runs multiple passes of optimization with emphasis on reducing registers and related combinational logic.

- **RuntimeOptimized**
  Runs minimal passes of optimization, trading design performance for faster run time.

- **NoBramPowerOpt**
  Runs all the default opt_design optimizations except block RAM Power Optimization.

- **Default**
  Runs opt_design with default settings.

**Using the -verbose Option**

To better analyze optimization results, use the -verbose option to see additional details of the logic affected by opt_design optimization.

The -verbose option is off by default due to the potential for a large volume of additional messages. Use the -verbose option if you believe it might be helpful.
RECOMMENDED: To improve tool run time for large designs, use the `-verbose` option only in shell or batch mode and not in the GUI mode.

IMPORTANT: The `opt_design` command operates on the in-memory design. If run multiple times, the subsequent run optimizes the results of the previous run. Therefore you might need to reload the implemented design before adding the `-verbose` option.

Logic Optimization Constraints

The Vivado Design Suite respects the `DONT_TOUCH` property during logic optimization. It does not optimize away nets with these properties. For more information, see the *Vivado Design Suite User Guide: Synthesis* (UG901) [Ref 8].

The `DONT_TOUCH` property is typically placed on leaf cells to prevent them from being optimized. `DONT_TOUCH` on a hierarchical cell preserves the cell boundary, but optimization might still occur within the cell.

Global Clock Buffer Insertion

Logic optimization conservatively inserts global clock buffers on high-fanout reset and clock nets, as long as it does not exceed 12 total global clock buffers in the design. For reset nets, the fanout must be above 50,000. For clock nets, the fanout must be 30 or greater.

The automatic clock buffer insertion is useful for bottom-up flows. Global clock buffer insertion is typically skipped for lower-level modules because they are out-of-context (OOC) and their clocks are not visible in the module containing them because they are black-boxed.

Power Optimization

Power optimization optimizes dynamic power using clock gating (optional). It can be used in both Project Mode and Non-Project Mode, and can be run after logic optimization or after placement to reduce power demand in the design. Power optimization includes Xilinx intelligent clock gating solutions that can reduce dynamic power in FPGA designs, but do not change the clocks or logic of the design.

For more information, see the *Vivado Design Suite User Guide: Power Analysis and Optimization* (UG907) [Ref 11].
Vivado Tools Power Analysis

The Vivado tools analyze all portions of the design, including legacy and third-party IP blocks. It also identifies output logic from sourcing registers that does not contribute to the result for each clock cycle.

Using Clock Enables (CEs)

The Vivado power optimizer takes advantage of the abundant supply of Clock Enables (CEs) available in the logic of Xilinx 7 series FPGA devices. The tools create fine-grain clock gating, or logic gating signals, that eliminate unnecessary switching activity in the register.

In addition, at the flip-flop level, CEs are actually gating the clock rather than selecting between the D input and feedback Q output of the flip-flop. This increases the performance of the CE input but also reduces clock power.

Intelligent Clock Gating

Intelligent clock gating also reduces power for dedicated block RAMs in either simple dual-port or true dual-port mode, as shown in Figure 2-14.

These blocks include several enables:

- Array enable
- Write enable
- Output register clock enable

Most of the power savings comes from using the array enable. The Vivado power optimizer implements functionality to reduce power when no data is being written and when the output is not being used.
power_opt_design

The `power_opt_design` command analyzes and optimizes the design. It analyzes and optimizes the entire design as a default. The command also performs intelligent clock gating to optimize power.

**power_opt_design Syntax**

```
power_opt_design [-quiet] [-verbose]
```

If you do not want to analyze and optimize the entire design, configure the optimizer with `set_power_opt`. This lets you specify the appropriate cell types or hierarchy to include or exclude in the optimization.

The syntax for `set_power_opt` is:

```
set_power_opt [-include_cells <args>] [-exclude_cells <args>] [-clocks <args>]
[-cell_types <args>] [-quiet] [-verbose]
```

**Note:** block RAM power optimization is skipped if it is run using `opt_design`.

Chapter 2: Implementing the Design

Placement

The Vivado Design Suite placer places cells from the netlist onto specific sites in the target Xilinx device. Like the other implementation commands, the Vivado placer works from, and updates, the in-memory design.

Design Placement Optimization

The Vivado placer simultaneously optimizes the design placement for:

- Timing slack: Placement of cells in timing-critical paths is chosen to minimize negative slack.
- Wirelength: Overall placement is driven to minimize the overall wirelength of connections.
- Congestion: The Vivado placer monitors pin density and spreads cells to reduce potential routing congestion.

Design Rule Checks

Before starting placement, Vivado implementation runs Design Rule Checks (DRCs), including user-selected DRCs from report_drc, and built-in DRCs internal to the Vivado placer. Internal DRCs check for illegal placement, such as Memory Interface Generator (MIG) cells without LOC constraints and I/O banks with conflicting IOSTANDARDs.

Clock and I/O Placement

After design rule checking, the Vivado placer places clock and I/O cells before placing other logic cells. Clock and I/O cells are placed concurrently because they are often related through complex placement rules specific to the targeted Xilinx device. Register cells with IOB properties are processed during this phase to determine which registers with an IOB value of TRUE should be mapped to I/O logic sites. If the placer fails to honor an IOB property of TRUE, a critical warning is issued.

Placer Targets

The placer targets at this stage of placement are:

- I/O ports and their related logic
- Global and local clock buffers
- Clock management tiles (MMCMs and PLLs)
- Gigabit Transceiver (GT) cells
Chapter 2: Implementing the Design

Placing Unfixed Logic

When placing unfixed logic during this stage of placement, the placer adheres to physical constraints, such as LOC properties and Pblock assignments. It also validates existing LOC constraints against the netlist connectivity and device sites. Certain IP (such as MIGs and GTs) are generated with device-specific placement constraints.

IMPORTANT: Due to the device I/O architecture, a LOC property often constrains cells other than the cell to which LOC has been applied. A LOC on an input port also fixes the location of its related I/O buffer, IDELAY, and ILOGIC. Conflicting LOC constraints cannot be applied to individual cells in the input path. The same applies for outputs and GT-related cells.

Clock Resources Placement Rules

Clock resources must follow the placement rules described in the 7 Series FPGAs Clocking Resources (UG472) [Ref 13] and UltraScale Architecture Clocking Resource (UG572) [Ref 14]. For example, an input that drives a global clock buffer must be located at a clock-capable I/O site, and must be located in the same upper or lower half of the device for 7 Series FPGAs, and in the same clock region for UltraScale devices. These clock placement rules are also validated against the logical netlist connectivity and device sites.

When Clock and I/O Placement Fails

If the Vivado placer fails to find a solution for the clock and I/O placement, the placer reports the placement rules that were violated, and briefly describes the affected cells. In some cases, the Vivado placer provisionally places cells at sites, and attempts to place other cells as it tries to solve the placement problem. The provisional placements often pinpoint the source of clock and I/O placement failure. Manually placing a cell that failed provisional placement might help placement converge.

TIP: Use place_ports to run the clock and I/O placement step first. Then run place_design. If port placement fails, the placement is saved to memory to allow failure analysis. For more information, run place_ports -help from the Vivado Tcl command prompt.

Global Placement, Detailed Placement, and Packing and Legalization

After Clock and I/O placement, the remaining placement phases consist of:

- Global placement
- Detailed placement
- Packing and legalization
**RECOMMENDED:** Run `report_timing` after placement to check the critical paths. Paths with very large negative slack might need manual placement, further constraining, or logic restructuring to achieve timing closure.

---

**place_design**

The `place_design` command runs placement on the design. Like the other implementation commands, `place_design` is re-entrant in nature. For a partially placed design, the Vivado placer uses the existing placement as the starting point instead of starting from scratch.

**place_design Syntax**

```shell
place_design [-directive <arg>] [-no_timing_driven] [-timing_summary]
[-unplace] [-post_place_opt] [-quiet] [-verbose]
```

**place_design Example Script**

```bash
# Run placement, save results to checkpoint, report timing estimates
place_design
write_checkpoint -force $outputDir/post_place
report_timing_summary -file $outputDir/post_place_timing_summary.rpt
```

The `place_design` example script places the in-memory design. It then writes a design checkpoint after completing placement, generates a timing summary report, and writes the report to the specified file.

**Using Directives**

Directives provide different modes of behavior for the `place_design` command. Only one directive may be specified at a time. The directive option is incompatible with other options.

The Placer has the most directives of all commands because placement typically has the most impact on overall design performance guidelines on which directives might benefit which types of designs:

- **Block placement** directives for designs with many block RAM, DSP blocks, or both.
- **NetDelay** directives for designs that anticipate many long-distance net connections and nets that fan out to many different modules.
- **SpreadLogic** directives for designs with very high connectivity that tend to create congestion.
- **ExtraPostPlacementOpt** for all design types.
- **SSI** directives for SSI designs that might benefit from different styles of partitioning to relieve congestion or improve timing.
**Placer Directives**

**IMPORTANT:** Placer directives are not currently supported in the UltraScale™ device architecture. If you try to supply a directive to the placer, it is ignored, and the placer continues with default settings.

Because placement typically has the greatest impact on overall design performance, the Placer has the most directives of all commands. Table 2-3 shows which directives might benefit which types of designs.

**Table 2-3: Directive Guidelines**

<table>
<thead>
<tr>
<th>Directive</th>
<th>Designs Benefitted</th>
</tr>
</thead>
<tbody>
<tr>
<td>BlockPlacement</td>
<td>Designs with many block RAM, DSP blocks, or both</td>
</tr>
<tr>
<td>ExtraNetDelay</td>
<td>Designs that anticipate many long-distance net connections and nets that fan out to many different modules</td>
</tr>
<tr>
<td>SpreadLogic</td>
<td>Designs with very high connectivity that tend to create congestion</td>
</tr>
<tr>
<td>ExtraPostPlacementOpt</td>
<td>All design types</td>
</tr>
<tr>
<td>SSI</td>
<td>SSI designs that might benefit from different styles of partitioning to relieve congestion or improve timing.</td>
</tr>
</tbody>
</table>

**Available Directives**

- **Explore**
  Higher placer effort in detail placement and post-placement optimization.

- **WLDrivenBlockPlacement**
  Wirelength-driven placement of RAM and DSP blocks. Override timing-driven placement by directing the Placer to minimize the distance of connections to and from blocks. This directive can improve timing to and from RAM and DSP blocks.

- **LateBlockPlacement**
  Defers detailed placement of RAMB and DSP blocks to the final stages of placement. Normally blocks are committed to valid sites early in the placement process. Instead, the Placer uses coarse block placements that might not align with proper columns, then places blocks at valid sites during detail placement.

- **ExtraNetDelay_high**
  Increases estimated delay of high fanout and long-distance nets. This directive can improve timing of critical paths that meet timing after place_design but fail timing in route_design due to overly optimistic estimated delays. Three levels of pessimism are supported: high, medium, and low. ExtraNetDelay_high applies the highest level of pessimism.

- **ExtraNetDelay_medium**
  Increases estimated delay of high fanout and long-distance nets. This directive can
improve timing of critical paths that meet timing after place_design but fail timing in route_design due to overly optimistic estimated delays. Three levels of pessimism are supported: high, medium, and low. ExtraNetDelay_medium applies the default level of pessimism.

- **ExtraNetDelay_low**
  Increases estimated delay of high fanout and long-distance nets. This directive can improve timing of critical paths that meet timing after place_design but fail timing in route_design due to overly optimistic estimated delays. Three levels of pessimism are supported: high, medium, and low. ExtraNetDelay_low applies the lowest level of pessimism.

- **SpreadLogic_high**
  Spreads logic throughout the device to avoid creating congested regions. Three levels are supported: high, medium, and low. SpreadLogic_high achieves the highest level of spreading.

- **SpreadLogic_medium**
  Spreads logic throughout the device to avoid creating congested regions. Three levels are supported: high, medium, and low. SpreadLogic_medium achieves a nominal level of spreading.

- **SpreadLogic_low**
  Spreads logic throughout the device to avoid creating congested regions. Three levels are supported: high, medium, and low. SpreadLogic_low achieves a minimal level of spreading.

- **ExtraPostPlacementOpt**
  Higher placer effort in post-placement optimization.

- **SSI_ExtraTimingOpt**
  Use an alternate algorithm for timing-driven partitioning across SLRs.

- **SSI_SpreadSLLs**
  Partition across SLRs and allocate extra area for regions of higher connectivity.

- **SSI_BalanceSLLs**
  Partition across SLRs while attempting to balance SLLs between SLRs.

- **SSI_BalanceSLRs**
  Partition across SLRs to balance number of cells between SLRs.

- **SSI_HighUtilSLRs**
  Force the placer to attempt to place logic closer together in each SLR.

- **RuntimeOptimized**
  Run fewest iterations, trade higher design performance for faster run time.

- **Quick**
  Absolute, fastest run time, non-timing-driven, performs the minimum required for a legal design.
• Default
  Run `place_design` with default settings.

**TIP:** *Use the -directive option to explore different placement options for your design.*

**Using the -unplace Option**

The `-unplace` option unplaces all cells and all ports in a design that do not have fixed locations. An object with fixed location has an `IS_LOC_FIXED` property value of TRUE.

**Using the -no_timing_driven Option**

The `-no_timing_driven` option disables the default timing driven placement algorithm. This results in a faster placement based on wire lengths, but ignores any timing constraints during the placement process.

**Using the -timing_summary Option**

After placement, an estimated timing summary is output to the log file. By default, the number reflects the internal estimates of the placer. For example:

```
INFO: [Place 30-746] Post Placement Timing Summary WNS=0.022. For the most accurate timing information please run report_timing.
```

For greater accuracy at the expense of slightly longer run time, you can use the `-timing_summary` option to force the placer to report the timing summary based on the results from the static timing engine.

```
INFO: [Place 30-100] Post Placement Timing Summary | WNS=0.236 | TNS=0.000 |
```

*where*

- WNS = Worst Negative Slack
- TNS = Total Negative Slack

**Using the -verbose Option**

To better analyze placement results, use the `-verbose` option to see additional details of the cell and I/O placement by the `place_design` command.

The `-verbose` option is off by default due to the potential for a large volume of additional messages. Use the `-verbose` option if you believe it might be helpful.

**Using the -post_place_opt Option**

Post placement optimization is a placement optimization that can potentially improve critical path timing at the expense of additional run time. The optimization is performed on
Chapter 2: Implementing the Design

A fully placed design with timing violations. For each of the top few critical paths, the placer tries moving critical cells to improve delay and commits new cell placements if they improve estimated delay. For designs with longer run times and relatively more critical paths, these placement passes may further improve timing.

This optimization can be run at any stage after placement, and can be particularly effective on a routed design. Be aware of the following when running this optimization on a routed design:

- Because the timing data reflects the actual routed delays, it ensures the optimization considers the most critical paths.
- When evaluating cell movements, the placer must estimate delays based on cell placements. It does not have access to the actual route delays.
- If new cell placements are committed, the related nets become unrouted and it is required to run route_design to route those nets.

See the following examples:

1. Run post placement optimization after placement:
   
   ```
   place_design
   place_design -post_place_opt
   ```
   
2. Run post placement optimization after routing:
   
   ```
   place_design
   phys_opt_design
   route_design
   place_design -post_place_opt
   route_design
   ```
   
3. Run multiple iterations of post placement optimization in a loop, after routing. For convenience, the implementation commands are wrapped in a Tcl proc called `runPPO` with arguments to choose the number of iterations and whether or not to enable `phys_opt_design` in each iteration:

   ```
   proc runPPO { {numIters 1} {enablePhysOpt 1} } {
     for {set i 0} {$i < $numIters} {incr i} {
       place_design -post_place_opt
       if {$enablePhysOpt != 0} {
         phys_opt_design
       }
       route_design
       if {([get_property SLACK [get_timing_paths ]] >= 0)} {break}; #stop if timing is met
     }
   }
   ```

   ```
   . . .
   place_design
   phys_opt_design
   route_design
   runPPO 4 1 ; # run 4 post-route iterations and enable phys_opt_design
   ```
Physical Optimization

Physical optimization performs timing-driven optimization on the negative-slack paths of a design. Physical optimization has two modes of operation: post-place and post-route.

In post-place mode, optimization occurs based on timing estimates based on cell placement. Physical optimization automatically incorporates netlist changes due to logic optimizations and places cells as needed.

In post-route mode, optimization occurs based on actual routing delays. In addition to automatically updating the netlist on logic changes and placing cells, physical optimization also automatically updates routing as needed.

Overall physical optimization is more aggressive in post-place mode, where there is more opportunity for logic optimization. In post-route mode, physical optimization tends to be more conservative to avoid disrupting timing-closed routing. Before running, physical optimization checks the routing status of the design to determine which mode to use, post-place or post-route.

If a design does not have negative slack, and a physical optimization with a timing based optimization option is requested, the command exits quickly without performing optimization.

Available Physical Optimizations

The Vivado tools perform the physical optimizations on the in-memory design, as shown in the table below.

**IMPORTANT:** Physical optimization can be limited to specific optimizations by choosing the corresponding command options. Only those specified optimizations are run, while all others are disabled, even those normally performed by default.

**High-Fanout Optimization**

High-Fanout Optimization works as follows:

1. High fanout nets, with negative slack within a percentage of the WNS, are considered for replication.
2. Loads are clustered based on proximity, and drivers are replicated and placed for each load cluster.
3. Timing is re-analyzed, and logical changes are committed if timing is improved.
4. After replication, the design is checked again for high fanout nets to replicate. If high fanout nets still exist, the replication process continues until there are no high fanout nets to optimize.

**Placement-Based Optimization**

Optimizes placement on the critical path by re-placing all the cells in the critical path to reduce wire delays.

**Routing Optimization**

Optimizes routing on critical paths by re-routing nets and pins with shorter delays.

**Rewiring**

Optimizes the critical path by swapping connections on LUTs to reduce the number of logic levels for critical signals. LUT equations are modified to maintain design functionality.
**Critical-Cell Optimization**

*Critical-Cell Optimization* replicates cells in failing paths. If the loads on a specific cell are placed far apart, the cell might be replicated with new drivers placed closer to load clusters. High fanout is not a requirement for this optimization to occur, but the path must fail timing with slack within a percentage of the worst negative slack.

**DSP Register Optimization**

*DSP Register Optimization* can move registers out of the DSP cell into the logic array or from logic to DSP cells if it improves the delay on the critical path.

**Block RAM Register Optimization**

*Block RAM Register Optimization* can move registers out of the block RAM cell into the logic array or from logic to block RAM cells if it improves the delay on the critical path.

**Shift Register Optimization**

The shift register optimization improves timing on negative slack paths between shift register cells (SRLs) and other logic cells.

If there are timing violations to or from shift register cells (SRL16E or SRLC32E), the optimization extracts a register from the beginning or end of the SRL register chain and places it into the logic fabric to improve timing. The optimization shortens the wirelength of the original critical path.

The optimization only moves registers from a shift register to logic fabric, but never from logic fabric into a shift register, because the latter never improves timing.

The prerequisites for this optimization to occur are:

- The SRL address must be one or greater, such that there are register stages that can be moved out of the SRL.
- The SRL address must be a constant value, driven by logic 1 or logic 0.
- There must be a timing violation ending or beginning from the SRL cell that is among the worst critical paths.

Certain circuit topologies are not optimized:

- SRLC32E that are chained together to form larger shift registers are not optimized.
- SRLC32E using a Q31 output pin.
- SRL16E that are combined into a single LUT with both O5 and O6 output pins used.
Registers moved from SRLs to logic fabric are FDRE cells. The FDRE and SRL INIT properties are adjusted accordingly as is the SRL address. Following is an example.

A critical path begins at a shift register (SRL16E) \texttt{srl\_inste}, as shown in Figure 2-15.

![Diagram of Critical Path Starting at Shift Register srl\_inste](image1)

\textit{Figure 2-15: Critical Path Starting at Shift Register srl\_inste}

After shift register optimization, the final stage of the shift register is pulled from the SRL16E and placed in the logic fabric to improve timing, as shown in Figure 2-16.

![Diagram of Critical Path after Shift Register Optimization](image2)

\textit{Figure 2-16: Critical Path after Shift Register Optimization}

The \texttt{srl\_inste} SRL16E address is decremented to reflect one fewer internal register stage. The original critical path is now shorter as the \texttt{srlopt} register is placed closer to the downstream cells and the FDRE cell has a relatively faster clock-to-output delay.
Critical Pin Optimization

Critical Pin Optimization performs remapping of logical LUT input pins to faster physical pins to improve critical path timing. A critical path traversing a logical pin mapped to a slow physical pin such as A1 or A2 is reassigned to a faster physical pin such as A6 or A5 if it improves timing. A cell with a LOCK_PINS property is skipped, and the cell retains the mapping specified by LOCK_PINS. Logical-to-physical pin mapping is given by the command get_site_pins.

Block RAM Enable Optimization

The block RAM enable optimization improves timing on critical paths involving power-optimized block RAMs.

Pre-placement block RAM power optimization restructures the logic driving block RAM read and write enable inputs, to reduce dynamic power consumption. After placement, the restructured logic may become timing-critical. The block RAM enable optimization reverses the enable-logic optimization to improve the slack on the critical enable-logic paths.

Hold-Fixing

Hold-Fixing attempts to improve slack of high hold violators by increasing delay on the hold critical path.

Retiming

Retiming improves the delay on the critical path by moving registers across combinational logic.

Forced Net Replication

Forced Net Replication forces the net drivers to be replicated, regardless of timing slack. Replication is based on load placements and requires manual analysis to determine if replication is sufficient. If further replication is required, nets can be replicated repeatedly by successive commands. Although timing is ignored, the net must be in a timing-constrained path to trigger the replication.

Clock Optimization

Inserts global buffers to create useful skew between critical path start and endpoints. To improve setup timing, buffers are inserted to delay the destination clock.

Routing Optimization

Performs routing optimization on timing-critical nets to reduce delay.
Physical Optimization Reports

Physical Optimization reports each net processed for optimization, and a summary of the optimization performed (if any).

**TIP:** Replicated objects are named by appending `_replica` to the original object name, followed by the replicated object count.

phys_opt_design

The `phys_opt_design` command runs physical optimization on the design. It can be run in post-place mode after placement and in post-route mode after the design is fully-routed.

**phys_opt_design Syntax**

```
phys_opt_design [-fanout_opt] [-placement_opt] [-routing_opt] [-rewire]
[-critical_cell_opt] [-dsp_register_opt] [-bram_register_opt]
[-bram_enable_opt] [-shift_register_opt] [-hold_fix] [-retime]
[-force_replication_on_nets <args>] [-directive <arg>]
[-critical_pin_opt] [-clock_opt] [-quiet] [-verbose]
```

**phys_opt_design Example Script**

```
open_checkpoint top_placed.dcp

# Run post-place phys_opt_design and save results
phys_opt_design
write_checkpoint -force $outputDir/top_placed_phys_opt.dcp
report_timing_summary -file $outputDir/top_placed_phys_opt_timing.rpt

# Route the design and save results
route_design
write_checkpoint -force $outputDir/top_routed.dcp
report_timing_summary -file $outputDir/top_routed_timing.rpt

# Run post-route phys_opt_design and save results
phys_opt_design
write_checkpoint -force $outputDir/top_routed_phys_opt.dcp
report_timing_summary -file $outputDir/top_routed_phys_opt_timing.rpt
```

The `phys_opt_design` example script runs both post-place and post-route physical optimization. First, the placed design is loaded from a checkpoint, followed by post-place `phys_opt_design`. The checkpoint and timing results are saved. Next the design is routed, with progress saved afterwards. That is followed by post-route `phys_opt_design`
and saving the results. Note that the same command `phys_opt_design` is used for both post-place and post-route physical optimization. No explicit options are used to specify the mode.

### Using Directives

Directives provide different modes of behavior for the `phys_opt_design` command. Only one directive may be specified at a time, and the directive option is incompatible with other options. The available directives are described below, and Table 2-5 provides a summary of post-place and post-route support.

- **Explore**
  Run different algorithms in multiple passes of optimization, including replication for very high fanout nets.

- **ExploreWithHoldFix**
  Run different algorithms in multiple passes of optimization, including hold violation fixing and replication for very high fanout nets.

- **AggressiveExplore**
  Similar to Explore but with different optimization algorithms and more aggressive goals.

- **AlternateReplication**
  Use different algorithms for performing critical cell replication.

- **AggressiveFanoutOpt**
  Uses different algorithms for fanout-related optimizations with more aggressive goals.

- **AlternateDelayModeling**
  Performs all optimizations using alternate algorithms for estimating net delays.

- **AddRetime**
  Performs the default `phys_opt_design` flow and adds register retiming.

- **AlternateFlowWithRetiming**
  Perform more aggressive replication and DSP and block RAM optimization, and enable register retiming.

- **Default**
  Run `phys_opt_design` with default settings.

Using the -verbose Option

To better analyze physical optimization results, use the -verbose option to see additional details of the optimizations performed by the phys_opt_design command.

The -verbose option is off by default due to the potential for a large volume of additional messages. Use the -verbose option if you believe it might be helpful.

**IMPORTANT:** The phys_opt_design command operates on the in-memory design. If run twice, the second run optimizes the results of the first run.

Physical Optimization Constraints

The Vivado Design Suite respects the DONT_TOUCH property during physical optimization. It does not perform physical optimization on nets or cells with these properties. Additionally, Pblock assignments are obeyed such that replicated logic inherits the Pblock assignments of the original logic. Timing exceptions are also copied from original to replicated cells.

For more information, see the Vivado Design Suite User Guide: Synthesis (UG901) [Ref 8].

The DONT_TOUCH property is typically placed on leaf cells to prevent them from being optimized. DONT_TOUCH on a hierarchical cell preserves the cell boundary, but optimization may still occur within the cell.
Chapter 2: Implementing the Design

Routing

The Vivado router performs routing on the placed design, and performs optimization on the routed design to resolve hold time violations.

The Vivado router starts with a placed design and attempts to route all nets. It can start with a placed design that is:

- Unrouted
- Partially routed
- Fully routed

For a partially routed design, the Vivado router uses the existing routes as the starting point, instead of starting from scratch. For a fully-routed design, the router checks for timing violations and attempts to re-route critical portions to meet timing.

Note: The re-routing process is commonly referred to as "rip-up and re-route."

The router provides options to route the entire design or to edit the routing of individual nets and pins. When routing the entire design, the flow is timing-driven, using full timing budgeting based on the timing constraints. When editing routes of nets and pins, the router uses fast, lightweight timing modeling for greater responsiveness in an interactive session.

RECOMMENDED: To avoid sacrificing performance for run time, it is best to run report_timing or to route the entire design after editing routes to ensure timing constraints are met.

Routing requires a one-time "run time hit" for initialization, even when editing routes of nets and pins. The initialization time increases with the size of the design and with the size of the device. The router does not need to be re-initialized unless the design is closed and reopened.

Design Rule Checks

Before starting routing, the Vivado tools run Design Rule Checks (DRC), including:

- User-selected DRCs from report_drc
- Built-in DRCs internal to the Vivado router engine
Routing Priorities

The Vivado Design Suite routes global resources first, such as:

- Clocks
- Resets
- I/O
- Other dedicated resources

This default priority is built into the Vivado router. The router then prioritizes data signals according to timing criticality.

Impact of Poor Timing Constraints

Post-routing timing violations are sometimes the result of incorrect timing constraints. Before you experiment with router settings, make sure that you have validated the constraints and the timing picture seen by the router. Validate timing and constraints by reviewing timing reports from the placed design before routing.

Common examples of poor timing constraints include:

- Cross-clock paths and multi-cycle paths in which hold timing causes route delay insertion
- Congested areas, which can be addressed by targeted fanout optimization in RTL synthesis or through physical optimization

**RECOMMENDED:** Review timing constraints and correct those that are invalid (or consider RTL changes) before exploring multiple routing options.

route_design

The `route_design` command runs routing on the design.

**route_design Syntax**

```
route_design [-unroute] [-release_memory] [-nets <args>] [-physical_nets]
             [-pin <arg>] [-directive <arg>] [-tns_cleanup]
             [-no_timing_driven] [-preserve] [-delay]
             -max_delay <arg> -min_delay <arg> [-timing_summary] [-quiet]
             [-verbose]
```

Using Directives

When routing the entire design, directives provide different modes of behavior for the `route_design` command. Only one directive may be specified at a time. The directive
option is incompatible with most other options to prevent conflicting optimizations. The following directives are available:

- **Explore**
  Allows the router to explore different critical path placements after an initial route.

- **NoTimingRelaxation**
  Prevents the router from relaxing timing to complete routing. If the router has difficulty meeting timing, it will run longer to try to meet the original timing constraints.

- **MoreGlobalIterations**
  Uses detailed timing analysis throughout all stages instead of just the final stages, and will run more global iterations even when timing improves only slightly.

- **HigherDelayCost**
  Adjusts the router's internal cost functions to emphasize delay over iterations, allowing a tradeoff of run time for better performance.

- **AdvancedSkewModeling**
  Uses more accurate skew modeling throughout all routing stages which may improve design performance on higher-skew clock networks.

- **RuntimeOptimized**
  Run fewest iterations, trade higher design performance for faster run time.

- **Quick**
  Absolute, fastest run time, non-timing-driven, performs the minimum required for a legal design.

- **Default**
  Run route_design with default settings.

**Trading Run Time for Better Routing**

The following directives are methods of trading run time for potentially better routing results:

- **NoTimingRelaxation**
- **MoreGlobalIterations**
- **HigherDelayCost**
- **AdvancedSkewModeling**

**Using other route_design options**

Following are more details on the route_design options and option values where applicable.

- **Using -nets**
  This limits operation to only the list of nets specified. The option requires an argument
that is a Tcl list of net objects. Note that the argument must be a net object, the value returned by `get_nets`, as opposed to the string value of the net names.

- **Using `-pin`**
  This limits operation only to the specified pin. The option requires an argument, which is the pin object. Note that the argument must be a pin object, the value returned by `get_pins`, as opposed to the string value of the pin name.

- **Using `-delay`**
  By default, the router routes individual nets and pins with the fastest run time, using available resources without regard to timing criticality. The `-delay` option directs the router to find the route with the smallest possible delay.

- **Using `-min_delay` and `-max_delay`**
  These options can be used only with the pin option and to specify a desired target delay in picoseconds. The `-max_delay` option specifies the maximum desired slow-max corner delay for the routing of the specified pin. Similarly the `-min_delay` option specifies the minimum fast-min corner delay. The two options can be specified simultaneously to create a desired delay range.

- **Using `-preserve`**
  This option routes the entire design while preserving existing routing. Without `-preserve`, the existing routing is subject to being unrouted and re-routed to improve critical path timing. This option is most commonly used when "pre-routing" critical nets, that is, routing certain nets first to ensure that they have best access to routing resources. After achieving those routes, the `-preserve` option ensures they will not be disrupted while routing the remainder of the design. Note that preserve is completely independent of the `FIXED_ROUTE` and `IS_ROUTE_FIXED` net properties. The route preservation lasts only for the duration of the `route_design` operation in which it is used.

- **Using `-unroute`**
  The `-unroute` option removes routing for the entire design or for nets and pins, when combined with the nets or pin options. The option does not remove routing for nets with `FIXED_ROUTE` properties. Removing routing on nets with `FIXED_ROUTE` properties requires the properties to be removed first.

- **Using `-timing_summary`**
  The router outputs a final timing summary to the log, based on its internal estimated timing which might differ slightly from the actual routed timing due to pessimism in the delay estimates. The `-timing_summary` option forces the router to call the Vivado static timing analyzer to report the timing summary based on the actual routed delays. This incurs additional run time for the static timing analysis.

- **Using `-tns_cleanup`**
  For optimal run time, the router focuses on optimizing the Worst Negative Slack (WNS) path as opposed to Total Negative Slack (TNS) paths. The `-tns_cleanup` option invokes an optional phase at the end of routing where the router attempts to fix the TNS paths, those failing paths other than the WNS path. Consequently, this option might reduce TNS at the expense of run time, but will not affect WNS. The
-tns_cleanup option is recommended when using post-route physical optimization to ensure that it focuses on the WNS path and does not waste effort on TNS paths that can be fixed by the router. This option is compatible with -directive.

- Using -physical_nets
  The -physical_nets option operates only on logic 0 and logic 1 routes. The option covers all logic constant values in the design and is compatible with the -unroute option. Because constant 0 and 1 tie-offs in the physical device have no exact correlation to logical nets, these nets cannot be routed and unrouted reliably using the -nets and -pin options.

- Using -release_memory
  After router initialization, router data is kept in memory to ensure optimal performance. This option forces the router to delete its data from memory and release the memory back to the operating system. This option should not be required for mainstream use and is provided in case router memory must be manually managed, for example, with extremely large designs.

- Using -no_timing_driven
  This option disables timing-driven routing and is used primarily for testing the routing feasibility of a design.
Chapter 2: Implementing the Design

Routing Example Script 1

# Route design, save results to checkpoint, report timing estimates
route_design
write_checkpoint -force $outputDir/post_route
report_timing_summary -file $outputDir/post_route_timing_summary.rpt

The route_design example script:

- Routes the design
- Writes a design checkpoint after completing routing
- Generates a timing summary report
- Writes the report to the specified file.

Routing is performed as part of an implementation run, or by running route_design after place_design as part of a Tcl script.

After routing is complete, the router reports a routing utilization summary and an estimated timing summary. An example of each is shown below.

Router Utilization Summary

Global Vertical Routing Utilization = 15.3424 %
Global Horizontal Routing Utilization = 16.3981 %
Routable Net Status*
  *Does not include unroutable nets such as driverless and loadless.
Run report_route_status for detailed report.
Number of Failed Nets = 0
Number of Unrouted Nets = 0
Number of Partially Routed Nets = 0
Number of Node Overlaps = 0

Timing Summary

[Route 35-57] Estimated Timing Summary | WNS=0.105 | TNS=0 | WHS=0.051 | THS=0

where:

- WNS = Worst Negative Slack
- TNS = Total Negative Slack
- WHS = Worst Hold Slack
- THS = Total Hold Slack
Routing Example Script 2

```tcl
# Get the nets in the top 10 critical paths, assign to $preRoutes
set preRoutes [get_nets -of [get_timing_paths -max_paths 10]]

# route $preRoutes first with the smallest possible delay
route_design -nets [get_nets $preRoutes] -delay

# preserve the routing for $preRoutes and continue with the rest of the design
route_design -preserve
```

In this example script, a few critical nets are routed first, followed by routing of the entire design. It illustrates routing individual nets and pins (nets in this case), which is typically done to address specific routing issues such as:

- Pre-routing critical nets and locking down resources before a full route.
- Manually unrouting non-critical nets to free up routing resources for more critical nets.

The first `route_design` command initializes the router and routes essential nets, such as clocks.

Routing Example Script 3

```tcl
route_design
# Unroute all the nets in u0/u1, and route the critical nets first
route_design -unroute [get_nets u0/u1/*]
route_design -delay -nets [get_nets $myCritNets]
route_design -preserve
```

The strategy in this example script illustrates one possible way to address timing failures due to congestion. In the example design, some critical nets represented by `$myCritNets` need routing resources in the same device region as the nets in instance `u0/u1`. The nets in `u0/u1` are not as timing-critical, so they are unrouted to allow the critical nets `$myCritNets` to be routed first, with the smallest possible delay. Then `route_design -preserve` routes the entire design. The `-preserve` switch preserves the routing of `$myCritNets` while the unrouted `u0/u1` nets are re-routed.

For a complete description of the Tcl reporting commands and their options, see the *Vivado Design Suite Tcl Command Reference Guide* (UG835) [Ref 15].
Incremental Compile

Incremental Compile is an advanced design flow for designs that are nearing completion, where small changes are required. After resynthesizing small changes, the flow:

- Speeds up place and route run time.
- Preserves QoR predictability by reusing prior placement and routing from a reference design. The flow is most effective when synthesis changes result in at least 95 percent similarity to the reference design.

A diagram of the Incremental Compile design flow is provided in Figure 2-17, below.

![Incremental Compile Design Flow](image)
Chapter 2: Implementing the Design

Incremental Compile Flow Designs

The Incremental Compile flow, shown in Figure 2-17, involves two different designs, the reference design and the current design.

Reference Design

The reference design is usually an earlier iteration or variation of the current design that has been synthesized, placed, and routed.

However, you can use a checkpoint that has any amount of placement, routing, or both. The reference design checkpoint (DCP) might be the product of many design iterations involving code changes, floorplanning, and revised constraints necessary to close timing.

After the current design is loaded, load the reference design checkpoint using the `read_checkpoint -incremental <dcp>` command. Loading the reference design checkpoint with the `-incremental` option enables the Incremental Compile design flow for subsequent place and route operations. For more information, see Examining the Similarity Between the Reference Design and the Current Design, page 82.

Current Design

The current design incorporates small design changes or variations from the reference design. These changes or variations can include:

- RTL changes
- Netlist changes
- Both RTL changes and netlist changes

Running Incremental Place and Route

The updated, current design is first loaded into memory. The reference design checkpoint is then loaded incrementally.

The key component of the Incremental Compile process is incremental place and route. The reference design checkpoint contains a netlist, constraints, and physical data including the placement and routing.

- The netlist in the current design is compared to the reference design to identify matching cells and nets.
- Placement from the reference design checkpoint is reused to place matching cells in the current design.
- Routing is reused to route matching nets on a per-load-pin basis. If a load pin disappears due to netlist changes, then its routing is discarded, otherwise it is reused. Therefore it is possible to have partially-reused routes.
Incremental placement and incremental routing might discard cell placements and net routes instead of reusing them, if it helps improve routability of the netlist or helps maintain performance comparable to that of the reference design.

Design objects that do not match between the reference design and the current design are placed after incremental placement is complete and routed after existing routing is reused.

**Nets with Multiple Fanouts**

The Vivado router performs fine-grained matching for nets with multiple fanouts, in which each routing segment can be reused or discarded as appropriate.

**Effectively Reusing Placement and Routing**

Effective reuse of the placement and routing from the reference design depends on the differences between the two designs. Even small differences can have a large impact.

**Impact of Small RTL Changes**

Although synthesis tries to minimize netlist name changes, sometimes small RTL changes such as the following can lead to very large changes in the synthesized netlist:

- Changing a constant value in the HDL code
- Increasing the size of an inferred memory
- Widening an internal bus

**Impact of Changing Constraints and Synthesis Options**

Similarly, changing constraints and synthesis options such as the following can also have a large impact on incremental placement and routing run time:

- Changing timing constraints and resynthesizing
- Preserving or dissolving logical hierarchy
- Enabling register re-timing

**Using phys_opt_design**

If the reference checkpoint was created with `phys_opt_design`, ensure that the incremental run also uses `phys_opt_design`. This captures the placement optimizations performed by `phys_opt_design` in the reference design and allows related routes to be reused. Unlike `place_design` and `route_design`, `phys_opt_design` does not have an incremental mode, but it does perform logic transformations in the revised design that are very similar to those of the reference design.

Note the netlist similarity between the post-route Reference Design and the Current Design. If the netlist matching seems suboptimal, it might be due to significant amounts of logic...
optimization from phys_opt_design. Therefore the post-place checkpoint might be a better reference design than the post-route checkpoint.

**Examining the Similarity Between the Reference Design and the Current Design**

Run report_incremental_reuse to examine and report the similarity between a reference design checkpoint file and the current design. The report_incremental_reuse command compares the netlist from the reference design checkpoint with the current in-memory design, and reports the percentage of matching of cells, nets, and ports.

A higher degree of design similarity results in more effective reuse of placement and routing from the reference design. The greater the percentage of similarity between the reference design and current design, the greater the opportunity for placement and routing reuse.

**Incremental Reuse Summary**

The reuse report is divided into two sections, the Netlist Similarity Summary and the Implementation Reuse Summary. The Netlist Similarity Summary shows how many logical objects in the current design match objects in the reference design. This indicates how logically similar the design is after updating it with small changes.

The Implementation Reuse Summary shows physical data reuse of matching logical objects, including what percentage of cells, ports, and nets are reused, along with their placement and routing information from the reference design. For cells that are not reused, it provides a breakdown of which cells are new cells in the netlist, those cells that do not exist in the reference design, and which cells have placements that must be discarded because their placements become illegal after updating the design. For nets, the report provides a breakdown of fully-reused routes, partially-reused routes, and nets that are new (that is, those nets that do not exist in the reference design).
An example reuse report is shown below.

</tbody>
</table>

In general, the higher the match percentage, the more placement and routing can be reused, and the faster place and route runs.

**Incremental Place and Route Metrics**

If 95% of the cells in the reference design and current design are similar, you can cut run times in half and maintain QoR predictability through use of incremental place and route instead of typical place and route methods.

The average run time improvement and QoR predictability decreases as similarity between the reference design and the current design decreases.

Below 85%, there might be little or no benefit to using the incremental place and route feature.

When cell reuse is too low, the Incremental Compile flow provides neither a run time nor a QoR predictability benefit, so it runs the default placement and routing. A Critical Warning is issued when this happens:
CRITICAL WARNING: [Vivado_Tcl 4-208] Running default Place and Route flow, as design objects reuse percentage is too low. Clearing placement and routing information, reused from last 'read_checkpoint -incremental' command.

Factors Affecting Run Time Improvement

Factors that can affect run time improvement include:

- The amount of change in timing-critical areas. If critical path placement and routing cannot be reused, more effort is required to preserve timing. Also, if the small design changes introduce new timing problems that did not exist in the reference design, higher effort and run time might be required, and the design might not meet timing.
- The initialization portion of the place and route run time. In short place and route runs, the initialization overhead of the Vivado placer and router might eliminate any gain from the incremental place and route process. For designs with longer run times, initialization becomes a small percentage of the run time.

Using Incremental Compile

In both Project Mode and Non-Project Mode, incremental place and route mode is entered when you load the reference design checkpoint using the `read_checkpoint -incremental <dcp_file>` command where `<dcp_file>` specifies the path and file name of the reference design checkpoint. Loading the reference design checkpoint with the `-incremental` option enables the Incremental Compile design flow for subsequent place and route operations. In Non-Project Mode, `read_checkpoint -incremental` should: (1) follow `opt_design` and; (2) precede `place_design`.

Using Incremental Compile in Non-Project Mode

To specify a design checkpoint file (DCP) to use as the reference design, and to run incremental place in Non-Project Mode:

1. Load the current design.
2. Run `opt_design`.
4. Run `place_design`.
5. Run `phys_opt_design` (optional). Run `phys_opt_design` if it was used in the reference design.
Chapter 2: Implementing the Design

6. Run `route_design`.

   ```
   link_design; # to load the current design
   opt_design
   read_checkpoint -incremental <dcp_file>
   place_design
   phys_opt_design; # if used in reference design
   route_design
   ```

Incremental placement relies on the ability of the Vivado tools to match design objects in the current design with design objects in the reference design. However, use of the following `opt_design` command options typically results in poor cell-name matching between the reference and current designs (which, in turn, results in poor matching of placement and routing data):

- `-resynth_area`
- `-resynth_seq_area`
- `-directive ExploreArea`
- `-directive ExploreAreaSequential`

**RECOMMENDED:** When running the Incremental Compile flow, avoid use of the four `opt_design` command options listed above.

**Using Incremental Compile in Project Mode**

In Project Mode, you can set the incremental compile option in the Design Runs window.

To set the incremental compile option:

1. Select a run in the Design Runs window.
2. Click **Set Incremental Compile** from the context menu.
3. In the Set Incremental Compile window, select a reference design checkpoint.

This enables incremental compile mode for the run.

**IMPORTANT:** When you choose a checkpoint from a design run, it is deleted if the design run is reset. If you want to choose a checkpoint from a design run, copy it into a separate directory before selecting it as your reference checkpoint.

For an example of the Implementation dialog box showing Incremental Compile settings, see Figure 2-18.
After incremental placement and routing are complete, you can review the messages generated by the Vivado tools.

**Note:** Implementation command directives and strategies are ignored when running the Incremental Compile flow because they have incompatible goals.
To disable incremental compile for the current run:

1. Clear the incremental_checkpoint property in the Set Incremental Compile window or the Implementation Run Properties window, or
2. Run the following command in the Tcl Console:
   
   ```
   reset_property INCREMENTAL_CHECKPOINT [current_run]
   ```

### Orphaned Route Segments

Some cells might have been eliminated from the current design, or moved during placement, leaving orphaned route segments from the reference design. If you are running in the Vivado IDE, you might see potentially problematic nets. These orphaned or improperly connected route segments are cleaned up during incremental routing by the Vivado router.

The following INFO message appears during placement.

```INFO: [Place 46-2] During incremental compilation, routing data from the original checkpoint is applied during place_design. As a result, dangling route segments and route conflicts may appear in the post place_design implementation due to changes between the original and incremental netlists. These routes can be ignored as they will be subsequently resolved by route_design. This issue will be cleaned up automatically in place_design in a future software release.
```

### Using Synplify Compile Points

The Incremental Compile flow is most effective when the revised and reference designs are most similar, preferably with at least 95 percent of the cells matching. Synthesis flows such as Synplify Compile Points minimize the amount of netlist changes resulting from RTL changes. Compile points are logical boundaries across which no optimization might occur. This sacrifices some design performance for predictability, but when combined with Incremental Compile, the resulting flow yields even more run time savings and predictability.

Synplify provides two different compile point flows: automatic and manual. In the automatic compile point mode, compile points are automatically chosen by synthesis, based on existing hierarchy and utilization estimates. This is a pushbutton mode. No user interaction is required besides enabling the flow. To enable, check the Auto Compile Point check box in the GUI or add the following setting to the Synplify project:

```set_option -automatic_compile_point 1```

The manual compile point flow offers more flexibility, but requires more interaction to choose compile points. The flow involves compiling the design, then using either the SCOPE editor Compile Points tab or the define_compile_point setting. For further information on compile point flows, see the Synplify online help.
Chapter 2: Implementing the Design

Saving Post-Reuse Checkpoints

After `read_checkpoint -incremental` applies the reference checkpoint to the current design, the incremental reuse data is retained throughout the flow. If a checkpoint is saved, then reloaded in the same or a separate Vivado Design Suite session, it remains in incremental compile mode. Consider the following command sequence:

```bash
opt_design; # optimize the current design
read_checkpoint -incremental reference.dcp; # apply reference data to current design
write_checkpoint incr.dcp; # save a snapshot of the current design
read_checkpoint incr.dcp
place_design
write_checkpoint top_placed.dcp; # save incremental placement result
route_design
```

Upon `read_checkpoint incr.dcp`, the Vivado tools determine that incremental data exists, and the subsequent `place_design` and `route_design` commands run incrementally.

Even if you exit and restart the Vivado Design Suite, in the following command sequence the `route_design` command is run in incremental mode, using the routing data from the original reference checkpoint `reference.dcp`:

```bash
read_checkpoint top_placed.dcp
phys_opt_design
route_design
```

Constraint Conflicts

Constraints of the revised design can conflict with the physical data of the reference checkpoint. When conflicts occur, constraints of the revised design take precedence. This is illustrated in the following example:

**Constraint Conflict Example**

A constraint assigns a fixed location `RAMB36_X0Y0` for a cell `cell_A`. However in the reference checkpoint `reference.dcp`, `cell_A` is placed at `RAMB36_X0Y1` and a different cell `cell_B` is placed at `RAMB36_X0Y0`.

After running `read_checkpoint -incremental reference.dcp`, `cell_A` is placed at `RAMB36_X0Y0` and `cell_B` is unplaced. The cell `cell_B` is placed during incremental placement.

**IMPORTANT:** You cannot use Pblocks when using incremental compile. Pblocks can create unmanageable placement conflicts.
Chapter 2: Implementing the Design

Incremental Compile Advanced Controls

There are three `read_checkpoint` options that provide control over cell placement reuse from a reference checkpoint. These options must be specified with the `read_checkpoint -incremental` option, as shown below.

- **only_reuse option**

  
  `-only_reuse <cell objects>`

  The `-only_reuse` option limits the cell placement reuse to the list of specified cells. The cells may be either leaf cells or hierarchical cells. Examples:

  - Only reuse the placement from a top-level instance `mem_ctrl_inst` within `routed.dcp`:
    ```
    read_checkpoint -incremental routed.dcp -only_reuse [get_cells mem_ctrl_inst]
    ```

  - Only reuse the block RAM placement within `routed.dcp`:
    ```
    read_checkpoint -incremental routed.dcp -only_reuse [get_cells -hier -filter {PRIMITIVE_TYPE =~ BMEM.bram.* }]
    ```

- **dont_reuse option**

  
  `-dont_reuse <cell objects>`

  The `-dont_reuse` option reuses all cell placement except for those in the specified list. The cells may be either leaf cells or hierarchical cells. Examples:

  - Reuse all placement from `routed.dcp` except for the cell placements from top-level instance `mem_ctrl_inst`:
    ```
    read_checkpoint -incremental routed.dcp -dont_reuse [get_cells mem_ctrl_inst]
    ```

  - Reuse all placement from `routed.dcp` except for the block RAM placement:
    ```
    read_checkpoint -incremental routed.dcp -dont_reuse [get_cells -hier -filter {PRIMITIVE_TYPE =~ BMEM.bram.*}]
    ```

- **fix_reuse option**

  The `-fix_reuse` option can be used with `-only_reuse` or `-dont_reuse` to lock down the placement of the reused cells automatically. Example:

  - Only reuse the block RAM placement within `routed.dcp`, and lock down the reused cell placement:
    ```
    read_checkpoint -incremental routed.dcp -only_reuse [get_cells -hier -filter {PRIMITIVE_TYPE =~ BMEM.bram.*}] -fix_reuse
    ```

  Reminder: in general, reused placement and routing can be modified. Therefore, `-fix_reuse` should be specified if modification is not desired.
After applying the RAM cell locations, the cells are affixed with IS_LOC_FIXED properties with value TRUE.

**Incremental Compile Advanced Analysis**

Vivado provides reporting, timing labels, and object properties for advanced reuse analysis.

**Reuse Reporting**

The report_incremental_reuse command provides options for more detailed analysis, similar to report_utilization.

- `cells <list of cells>`

The -cells option limits the reuse reporting to the list of given cells instead of reporting reuse of the entire design.

Example: Limit the reuse reporting to only block RAM:

```
report_incremental_reuse -cells [get_cells -hierarchical -filter { PRIMITIVE_TYPE =~ BMEM.bram.* }]
```

**Incremental Reuse Summary**

1. Netlist Similarity Summary

```
+------------------+-+-----+-----+-------------+
|      Type        | Count | Total| Percentage  |
+------------------+-+-----+-----+-------------+
| Matched Cells    | 16   | 16   | 100.00    |
| Matched Ports    | 71   | 71   | 100.00    |
| Matched Nets     | 6154 | 6171 | 99.72     |
+------------------+-+-----+-----+-------------+
```

2. Implementation Reuse Summary

```
+------------------+-+-----+-----+-------------+
|      Type        | Count | Total| Percentage  |
+------------------+-+-----+-----+-------------+
| Reused Cells     | 16   | 16   | 100.00    |
| Non-Reused Cells | 0    | 16   | 0.00      |
+------------------+-+-----+-----+-------------+
```

The -hierarchical option displays a breakdown of cell reuse at each hierarchical level. Following is an example of report_incremental_reuse -hierarchical:

**Note:** The sample report has been truncated horizontally and vertically to fit.
Hierarchical Implementation Reuse Summary

1. Summary

----------

<table>
<thead>
<tr>
<th>Instance</th>
<th>Module</th>
<th>Reused</th>
<th>New</th>
<th>Discarded(Illegal)*</th>
</tr>
</thead>
<tbody>
<tr>
<td>bft (bft)</td>
<td>(top)</td>
<td>3607</td>
<td>9</td>
<td>2</td>
</tr>
<tr>
<td>arnd1</td>
<td>round_1</td>
<td>256</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>transformLoop[0].ct</td>
<td>coreTransform_43</td>
<td>32</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>transformLoop[1].ct</td>
<td>coreTransform_38</td>
<td>32</td>
<td>0</td>
<td>0</td>
</tr>
<tr>

<td>32</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

* Discarded illegal placement due to netlist changes
** Discarded to improve timing
*** Discarded placement by user
**** Discarded due to its control set source is unguided
***** Discarded due to its connectivity has Loc Fixed Insts

The reuse status of each cell is reported, beginning with the top-level hierarchy, then covering each level hierarchy contained within that level. The report progresses to the lowest level of hierarchy contained within the first submodule, then moves on to the next one.

In this example, the top level cell is bft with a cumulative reuse total of 3607 cells with 9 new cells. The row with bft in parentheses show the cell reuse status contained within bft and but not its submodules. Of the 3607 cells, only 210 are within bft and the remainder are within its submodules. However all 9 new cells are within bft. Within bft is a submodule arnd1 containing 256 reused cells, and no cells within arnd1 itself, only in submodules transformLoop[0].ct, transformLoop[1].ct, and so on.

There are 5 columns indicating cell reuse status at each level, although only the first one Discarded(Illegal) is shown. These columns have footnote references in the report with further reasons for discarding reused placement.

* Discarded illegal placement due to netlist changes
** Discarded to improve timing
*** Discarded placement by user
**** Discarded due to its control set source is unguided
***** Discarded due to its connectivity has Loc Fixed Insts

---

Chapter 2: Implementing the Design
Instead of reporting all hierarchical levels, you can use the -hierarchical_depth option to limit the number of submodules to an exact number of levels. The following is the previous example, adding -hierarchical_depth of 1:

```
report_incremental_reuse -hierarchical -hierarchical_depth 1
```

### 1. Summary

<table>
<thead>
<tr>
<th>Instance</th>
<th>Module</th>
<th>Reused</th>
<th>New</th>
<th>Discarded(Illegal)*</th>
</tr>
</thead>
<tbody>
<tr>
<td>bft</td>
<td>(top)</td>
<td>3607</td>
<td>9</td>
<td>2</td>
</tr>
</tbody>
</table>

This limits reporting to the top level bft. If you had used a -hierarchical_depth of 2, the top and each level of hierarchy contained within bft would be reported, but nothing below those hierarchical cells.

**Hierarchical Implementation Reuse Summary**

1. Summary

</tbody>
</table>

### Timing Reports

After completing an incremental place and route, you can analyze timing with details of cell and net reuse. Objects are tagged in timing reports to show the level of physical data reuse. This identifies whether or not your design updates are affecting critical paths.

To see incremental flow details in timing reports, use the report_timing -label_reused option. This generates a report showing reuse labels on input and output
pins, indicating the amount of physical data reused for the cell and net of the pin. The following label descriptions are included as a legend in the timing report:

- **(R):**
  Both the cell placement and net routing are reused.

- **(NR):**
  Neither the cell placement nor the routing to the pin is reused.

- **(PNR):**
  The cell placement is reused but the routing to the pin is not reused.

- **(N):**
  The pin, cell, or net is a new design object, not present in the reference design.

See the following example.

<table>
<thead>
<tr>
<th>Object</th>
<th>Properties</th>
</tr>
</thead>
<tbody>
<tr>
<td>(NR) SLICE_X46Y42</td>
<td>FDRE (Prop_fdre_C_Q) 0.259   -1.862 r fftI/fifoSel_reg[5]/Q net (fo=8, estimated) 0.479 -1.383 fftI/n_fifoSel_reg[5]</td>
</tr>
<tr>
<td>(R) SLICE_X46Y43</td>
<td>LUT4 (Prop_lut4_I1_O) 0.043   -1.340 r fftI/wbDOut_reg[31]i5/i1</td>
</tr>
<tr>
<td>(PNR) SLICE_X44Y39</td>
<td>MUXF7 (Prop_muxf7_S_O) 0.154   0.140 r fftI/wbDOut_reg[0]i1/S net (fo=1, routed) 0.000 0.140 fftI/wbDOut_reg[0]i1/D</td>
</tr>
</tbody>
</table>

**Object Properties**

The `read_checkpoint -incremental` command assigns two cell properties which are useful for analyzing incremental flow results using scripts or interactive Tcl commands.

- **IS_REUSED:** A boolean property on cell, port, net, and pin objects. The property is set to TRUE on the respective object if any of the following incremental data is reused:
  - A cell placement
  - A package pin assignment for a port
  - Any portion of the routing for a net
  - Routing to a pin

- **REUSE_STATUS:** A string property on cells and nets denoting the reuse status after incremental placement and routing.

Possible values for cells are:

- New
- Reused
- Discarded placement to improve timing
- Discarded illegal placement due to netlist changes

Possible values for nets are:

- REUSED
- NON_REUSED
- PARTIALLY_REUSED
Chapter 3

Analyzing and Viewing Implementation Results

Monitoring the Implementation Run

Monitoring the implementation run allows you to:

• Read the compilation information.
• Review warnings and errors in the Messages window.
• View the Project Summary.
• Open the Design Runs window.

Monitor the status of a Synthesis or Implementation run in the Log window.

Viewing the Run Status Display

The status of a run that is in progress can be displayed in two ways for synthesis and implementation runs. These status displays show that a run is in progress. They allow you to cancel the run if desired.

• You can find a run status indicator in the project status bar at the upper right corner of the Vivado® IDE, as shown in the figure below. The run status indicator displays a scrolling bar to indicate that the run is in process. You can use the Cancel button to end the run.

![Run Status Indicator](image)

*Figure 3-1: Run Status Indicator*

• You can also find a run status indicator in the Design Runs window, as shown at the bottom left of the figure below. It displays a circular arrow (noted in red in the figure below) to indicate that the run is in process. You can select the run and use the Reset Run command from the popup menu to cancel the run.
Cancelling/Resetting the Run

If you cancel a run that is in-progress, using either the Cancel button or the Reset Run command, the Vivado IDE prompts you to delete any run files created during the cancelled run, as shown in the figure below.

Select **Delete Generated Files** to clear the run data from the local project directories.

**RECOMMENDED:** Delete any data created as a result of a cancelled run to avoid conflicts with future runs.

### Viewing the Log in the Log Window

The Log window opens in the Vivado IDE after you launch a run. It shows the standard output messages. It also displays details about the progress of each individual implementation process, such as `place_design` and `route_design`.

The Log window, shown the figure below, can help you understand where different messages originate to aid in debugging the implementation run.
Chapter 3: Analyzing and Viewing Implementation Results

Pausing Output

Click Pause to pause the output to the Log window. Pausing allows you to read the log while implementation continues running.

Displaying the Project Status

The Vivado IDE uses several methods to display the project status and which step to take next. The project status reports only the results of the major design tasks.

The project status is displayed in the Project summary and the Status bar. It allows you to immediately see the status of a project when you open the project, or while you are running the design flow commands, including:

- RTL elaboration
- Synthesis
- Implementation
- Bitstream generation

Viewing Project Status in the Project Status Bar

The project status is displayed in the project status bar in the upper-right corner of the Vivado IDE.

As the run progresses through the Synthesize, Implement, and Write Bitstream commands, the Project Status Bar changes to show either a successful or failed attempt. Failures are displayed in red text.

Viewing Out-of-Date Status

If source files or design constraints change, and either synthesis or implementation was previously completed, the project might be marked as Out-of-Date, as shown in the figure below.

The project status bar shows an Out-of-Date status. Click more info to display which aspects of the design are out of date. It may be necessary to rerun implementation, or both synthesis and implementation.
Forcing Runs Up-to-Date

Click Force-up-to-date to force the implementation or synthesis runs up to date. Use Force-up-to-date if you changed the design or constraints, but still want to analyze the results of the current run.

TIP: The Force-up-to-date command is also available from the popup menu of the Design Runs window when an out-of-date run is selected.

For more information, see the Vivado Design Suite User Guide: Using the Vivado IDE (UG893) [Ref 3].

Moving Forward After Implementation

After implementation has completed, for both Project Mode and Non-Project Mode, the direction you take the design next depends on the results of the implementation.

• Is the design fully placed and routed, or are there issues that need to be resolved?
• Have the timing constraints and design requirements been met, or are their additional changes required to complete the design?
• Are you ready to generate the bitstream for the Xilinx® part?
Chapter 3: Analyzing and Viewing Implementation Results

Recommended Steps After Implementation

The recommended steps after implementation are:

1. Review the implementation messages.
2. Review the implementation reports to validate key aspects of the design:
   - Timing constraints are met (report_timing_summary).
   - Utilization is as expected (report_utilization).
   - Power is as expected (report_power).
3. Write the bitstream file.
   Writing the bitstream file includes a final DRC to ensure that the design does not violate any hardware rules.
4. If any design requirements have not been met:
   a. In Project Mode, open the implemented design for further analysis.
   b. In Non-Project Mode, open a post-implementation design checkpoint.

For more information on analysis of the implemented design, see the Vivado Design Suite User Guide: Design Analysis and Closure Techniques (UG906) [Ref 10].

Moving Forward in Non-Project Mode

In Non-Project Mode, the Vivado Design Suite generated messages for the design session, and wrote the messages to the Vivado log file (vivado.log). Examine this log file and the reports generated from the design data to view an accurate assessment of the current project state.

Moving Forward in Project Mode

In Project Mode, the Vivado Design Suite:

- Displays the messages from the log file in the Messages window.
- Automates the creation and delivery of numerous reports for you to review.

In Project Mode, after an implementation run is complete in the Vivado IDE, you are prompted for the next step, as shown in the figure below.
In the Implementation Completed dialog box:

1. Select the appropriate option:
   - Open Implemented Design
     Imports the netlist, design constraints, the target part, and the results from place
     and route into the Vivado IDE for design analysis and further work as needed.
   - Generate Bitstream
     Launches the Generate Bitstream dialog box. For more information, see the Vivado
     Design Suite User Guide: Programming and Debugging (UG908) [Ref 12].
Chapter 3: Analyzing and Viewing Implementation Results

- **View Reports**
  Opens the Reports window for you to select and view the various reports produced by the Vivado tools during implementation. For more information, see Viewing Implementation Reports, page 103.

2. Click **OK**.

---

**Viewing Messages**

**IMPORTANT:** Review all messages. The messages might suggest ways to improve your design for performance, power, area, and routing. Critical warnings might also expose timing constraint problems that must be resolved.

---

**Viewing Messages in Non-Project Mode**

In Non-Project Mode, review the Vivado log file (`vivado.log`) for:

- The commands that you used during a single design session
- The results and messages from those commands

**RECOMMENDED:** Open the log file in the Vivado text editor and review the results of all commands for valuable insights.

---

**Viewing Messages in Project Mode**

In Project Mode, the Messages window, shown in the figure below, displays a filtered list of the Vivado log. This list includes only the main messages, warnings, and errors. The Messages window sorts by feature, and includes toolbar options to filter and display only specific types of messages.
Use the following features when viewing messages in Project Mode:

- Click the expand and collapse tree widgets to view the individual messages.
- Check the appropriate check box in the banner to display errors, critical warnings, warnings, and informational messages in the Messages window.
- Select a linked message in the Messages window to open the source file and highlight the appropriate line in the file.
- Run Search for Answer Record from the Messages window popup menu to search the Xilinx Customer Support database for answer records related to a specific message.

### Incremental Compile Messages

The Vivado tools log file reports incremental placement and routing summary results from Incremental Compile.

#### Incremental Placement Summary

The following example of the Incremental Placement Summary includes a final assessment of:

- Cell placement reuse
- Run time statistics
Chapter 3: Analyzing and Viewing Implementation Results

<table>
<thead>
<tr>
<th>Incremental Placement Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reused instances</td>
</tr>
<tr>
<td>Non-reused instances</td>
</tr>
<tr>
<td>%similarity</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Incremental Placement Runtime Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Initialization time (elapsed secs)</td>
</tr>
<tr>
<td>Incremental Placer time (elapsed secs)</td>
</tr>
</tbody>
</table>

**Incremental Routing Summary**

The Incremental Routing Summary displays reuse statistics for all nets in the design. The categories reported include:

- **Fully Reused**
  The entire routing for a net is reused from the reference design.

- **Partially Reused**
  Some of the routing for a net from the reference design is reused. Some segments are re-routed due to changed cells, changed cell placements, or both.

- **New/Unmatched**
  The net in the current design was not matched in the reference design.

<table>
<thead>
<tr>
<th>Incremental Routing Reuse Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>----------------</td>
</tr>
<tr>
<td>Fully reused nets</td>
</tr>
<tr>
<td>Partially reused nets</td>
</tr>
<tr>
<td>Non Reused nets</td>
</tr>
</tbody>
</table>

**Viewing Implementation Reports**

The Vivado Design Suite generates many types of reports, including reports on:

- Timing, timing configuration, and timing summary
- Clocks, clock networks, and clock utilization
- Power, switching activity, and noise analysis
When viewing reports, you can:

- Browse the report file using the scroll bar.
- Click **Find** or **Find in Files** to search for specific text.
- Click **Go to the Beginning** to scroll to the beginning file.
- Click **Go to the End** to scroll to end of the file.

**Reporting in Non-Project Mode**

In Non-Project Mode, you must run these reports manually.

- Use Tcl commands to create an individual report.
- Use a Tcl script to create a series of reports.

**Example Tcl Script**

The following Tcl script runs a series of reports and saves them to a Reports folder:

```tcl
# Report the control sets sorted by clk, clkEn
report_control_sets -verbose -sort_by {clk clkEn} -file C:/Report/cntrl_sets.rpt
# Run Timing Summary Report for post implementation timing
report_timing_summary -file C:/Reports/post_route_timing.rpt -name time1
# Run Utilization Report for device resource utilization
report_utilization -file C:/Reports/post_route_utilization.rpt
```

**Opening Reports in a Vivado IDE Window**

You can open these reports in a Vivado IDE window. In the example Tcl script above, the `report_timing_summary` command:

- Uses the `-file` option to direct the output of the report to a file.
- Uses the `-name` option to direct the output of the report to a Vivado IDE window.

**Figure 3-9** shows an example of a report opened in a Vivado IDE window.

---

**TIP:** The directory to which the reports are to be written must exist before running the report, or the file cannot be saved, and an error message will be generated.
Getting Help With Implementation Reports

Use the Tcl help command in the Vivado IDE or at the Tcl command prompt.

For a complete description of the Tcl reporting commands and their options, see the Vivado Design Suite Tcl Command Reference Guide (UG835) [Ref 15].

Reporting in Project Mode

In Project Mode, many reports are generated automatically. View report files in the Reports window, shown in Figure 3-8.

The Reports window usually opens automatically after synthesis or implementation commands are run. If the window does not open do one of the following:

• Select the Reports link in the Project Summary
• Select Windows > Reports

TIP: The tcl.pre and tcl.post options of an implementation run let you output custom reports at each step in the process. These reports are not listed in the Reports window, but can be customized to meet your specific needs. For more information, see Changing Implementation Run Settings, page 28.

Figure 3-8: Example Reports View
The reports available from the Reports window contain information related to the run. The selected report opens in text form in the Vivado IDE, as shown in the figure below.

![Control Sets Report](image)

**Figure 3-9: Control Sets Report**

**Cross-Probing from Reports**

In both Project Mode and Non-Project Mode, the Vivado IDE supports cross-probing between reports and the associated design data in different windows (for example, the Device window).

- You generate the report using a menu command or Tcl command.
- Text reports do not support cross-probing.

For example, the Reports window includes a text-based Timing Summary Report under Route Design (as shown in Figure 3-8).

When analyzing timing, it is helpful to see the design data associated with critical paths, including placement and routing resources in the Device window.
To regenerate the report in the Vivado IDE, select **Tools > Timing > Report Timing Summary**. The resulting report allows you to cross-probe among the various views of the design.

**Cross-Probing Between Timing Report and Device Window Example**

Figure 3-10 shows an example of cross-probing between the Timing Summary report and the Device window. The following steps took place in this Non-Project Mode example:

- A post-route design checkpoint was opened in the Vivado IDE.
- The Timing Summary report was generated and opened using `report_timing_summary -name`.
- The Routing Resources were enabled in the Device window.
- When the timing path was selected in the Timing Summary report, the path was automatically cross-probed in the Device window, as shown in the figure below.

![Cross-Probing Between Timing Report and Device Window](image)

**Figure 3-10:** Cross-Probing Between Timing Report and Device Window

For more information on analyzing reports and strategies for design closure, see the *Vivado Design Suite User Guide: Design Analysis and Closure Techniques* (UG906) [Ref 10].
Modifying Placement

The Vivado tools track two states for placed cells: Fixed and Unfixed, which describes the way in which the Vivado tools view placed cells in the design.

Fixed Cells

Fixed cells have been placed by a designer, or have been imported from a constraints file.

- The Vivado Design Suite treats these placed cells as Fixed.
- Fixed cells are not moved unless directed to do so.
- The FF in Figure 3-11 is shown in orange (default) to indicate that it is Fixed.
Unfixed Cells

Unfixed cells have been placed by the Vivado tools in implementation, during the `place_design` command, or on execution of one of optimization commands.

- The Vivado Design Suite treats these placed cells as Unfixed (or loosely placed).
- These cells can be moved by the implementation tools as needed in design iterations.
- The LUT in the figure below is shown in blue (default) to indicate that it is Unfixed.

![Logic Placed in a Slice](image)

**Figure 3-11: Logic Placed in a Slice**

Both LOCS and BELS can be fixed. The placement above generates the following constraints:

```plaintext
set_property BEL BFF [get_cells {fftEngine/control_reg_reg[1]}]
set_property LOC SLICE_X1Y199 [get_cells {fftEngine/control_reg_reg[1]}]
```

There is no placement constraint on the LUT. Its placement is unfixed, indicating that the placement should not go into the XDC.
Fixing Placer Placed Logic

To fix cells placed by the Vivado placer in the Vivado IDE:

1. Select the cells.
2. Choose **Fix Cells** from the popup menu.

To fix cell placement with Tcl, use a command of this form:

```tcl
set_property is_bel_fixed TRUE [get_cells [list {fftEngine/control_reg_reg[1]_i_1}]]
set_property is_loc_fixed TRUE [get_cells [list {fftEngine/control_reg_reg[1]_i_1}]]
```

For more information on Tcl commands, see the *Vivado Design Suite Tcl Command Reference Guide* (UG835) [Ref 9], or type `<command> -help`.

Placing and Moving Logic by Hand

You can place and move logic by hand.

- If the cell is already placed, drag and drop it to a new location.
- If the cell is unplaced:
  - a. Enter **Create BEL Constraint Instance Drag & Drop** mode.
  - b. Drag the logic from the Netlist window, or from the Timing Report window, onto the Device window.

  The logic snaps to a new legal location.

Hand placing logic can be slow. The constraints are fragile with respect to design changes, because the cell name is used in the constraint.

Modifying Routing

The Device View allows you to modify the routing for your design. You can Unroute, Route, and Fix Routing on any individual net.

To Unroute, Route, or Fix Routing on a net:

1. Open Device View.
2. Select the net.
   - Unrouted nets are indicated by a red flyline.
   - Partially routed nets are highlighted in yellow.
3. Right-click and select **Unroute**, **Route**, or **Fix Routing**.

- **Unroute** and **Route**: Calls the router in re-entrant mode to perform the operation on the net. For more information, see *route_design*, page 73, in Chapter 2.

- **Fix Routing**: Deposits the route, marks it fixed in the route database, and fixes the LOC and BEL of the driver and the load of the net. You can also enter Assign Routing Mode, which allows you to route a net manually. For more information, see **Manual Routing**, below.

**TIP:** All net commands are available from the context menu on a net.

---

**Manual Routing**

Manual routing allows you to select specific routing resources for your nets. This gives you complete control over the routing paths that a signal is going to take. Manual routing does not invoke *route_design*. Routes are directly updated in the route database.

You might want to use manual routing when you want to precisely control the delay for a net. For example, assume a source synchronous interface, in which you want to minimize routing delay variation to the capture registers in the device. To accomplish this, you can assign LOC and BEL constraints to the registers and I/Os, and then precisely control the route delay from the IOB to the register by manual routing the nets.

---

**Figure 3-12:** Modify Routing
Manual routing requires detailed knowledge of the device interconnect architecture. It is best used for a limited number of signals and for short connections.

**Manual Routing Rules**

Observe these rules during manual routing:

- The driver and the load require a LOC constraint and a BEL constraint.
- Branching is not allowed during manual routing, but you can implement branches by starting a new manual route from a branch point.
- LUT loads must have their pins locked.
- You must route to loads that are not already connected to a driver.
- Only complete connections are permitted. Antennas are not allowed.
- Overlap with existing unfixed routed nets is allowed. Run route_design after manual routing to resolve any conflicts due to overlapping nets.

**Entering Assign Routing Mode**

To enter Assign Routing Mode:

1. Open Device View.
2. Be sure that Routing Resources in the Device window is selected.
3. Enable the Layers for Unrouted Net and Partially Routed Net in the Device Options Layers view, shown in the figure below.
4. Select the net that requires routing.
   - Unrouted nets are indicated by a red flyline.
   - Partially routed nets are highlighted in yellow.
5. Right-click and select **Enter Assign Routing Mode**.
   The Target Load Cell Pin window opens.
6. Optionally, select a load cell pin to which you want to route.
7. Click **OK**.
Note: To display partially routed or unrouted nets in the Device View, you must ensure that those layers are selected in the Device Options menu, shown in the figure below.

![Device Options Pull-Out Menu](image)

Figure 3-14: Device Options Pull-Out Menu

You are now in Manual Routing Mode. A Routing Assignment window, shown in the figure below, appears next to the Device View.
Chapter 3: Analyzing and Viewing Implementation Results

Routing Assignment Window

The routing assignment window is divided into three sections, described as follows:

Options Section

The Options section, shown in the figure below, controls the settings for the Routing Assignment window.

- The Number of hops value allows you to specify the number of routing hops that can be assigned for Neighbor Nodes. This also affects the Neighbor Nodes displayed. If the number of hops is greater than 1, only the last node of the route is displayed in the Neighbor Nodes section.
• The **Maximum number of neighbors** value allows you to limit the number of neighbor nodes that are displayed in the Neighbor Nodes section. Only the last node of the route is displayed.

• The **Allow overlap with unfixed nets** switch controls whether overlaps of assigned routing with existing unfixed routing is allowed. Any overlaps need to be resolved by running the `route_design` command after fixed route assignment.

The Options section is hidden by default. To show the Options section, click **Show**.

**Assigned Nodes Section**

The Assigned Nodes section shows the nodes that already have assigned routing. Each assigned node is displayed as a separate line item.

In the Device View, nodes with assigned routing are highlighted in orange. Any gaps between assigned nodes are shown in the Assigned nodes section as a GAP line item. To auto-route gaps:

1. Right-click a net gap in the Assigned Nodes section.
2. Select **Auto-route** from the context sensitive menu.

To assign the next routing segment, select an assigned node before or after a gap, or the last assigned node in the Assigned Nodes section.

**Neighbor Nodes Section**

As shown in the figure below, the Neighbor Nodes Section displays the allowed neighbor nodes, highlights the current selected nodes (in white), and highlights the allowed neighbor nodes (white dotted) in the Device View.
Assigning Routing Nodes

Once you have decided which Neighbor Node to assign for your next route segment, you can:

- Right-click the node in the Neighbor Nodes section and select Assign Node.
- Double-click the node in the Neighbor Nodes section.
- Click the node in the Device View

After you have assigned routing to a Neighbor Node, the node is displayed in the assigned nodes section and highlighted in orange in the Device View.

Assign nodes until you have reached the load, or until you are ready to assign routing with a gap.

Figure 3-17: Assign Next Routing Segment
Chapter 3: Analyzing and Viewing Implementation Results

Un-Assigning Routing Nodes

To un-assign nodes:

1. Go to the Assigned Nodes pane of the Routing Assignment window.
2. Select the nodes to be un-assigned.
3. Right-click and select Remove.

The nodes are removed from the assignment.

Exiting Assign Routing Mode

To finish the routing assignment and exit Assign Routing Mode:

Click the Assign Routing button in the Routing Assignment window.

The Assign Routing Window is displayed, as shown in the figure below, allowing you to verify the assigned nodes before they are committed.

![Assign Routing Confirmation](image)

Figure 3-18: Assign Routing Confirmation

Cancelling Out of Assign Routing Mode

If you are not ready to commit your routing assignments, you can cancel out of the Assign Routing Mode using one of the following methods:

- Click Exit Mode in the Routing Assignment window, or
- Right-click in the Device View and select Exit Assign Routing Mode.

When the routes are committed, the driver and load BEL and LOC are also fixed.
Verifying Assigned Routes

- Assigned routes appear as dotted green lines in the Device View.
- Partially assigned routes appear as dotted yellow lines in the Device view.

The figure below shows an example of an assigned and partially assigned route.

![Assigned Partially Assigned Routing](image)

Figure 3-19: Assigned Partially Assigned Routing

Locking Cell Inputs on LUT Loads

You must ensure that the inputs of LUT loads to which you are routing are not being swapped with other inputs on those LUTs. To do so, lock the cell inputs of LUT loads as follows:

1. Open Device View.
2. Select the load LUT.
3. Right-click and select **Lock Cell Input Pins**.

The equivalent TCL command is:

```
set_property LOCK_PINS {NAME:BEL_PIN} <cell object>
```
Branching

When assigning routing to a net with more than one load, you must route the net in the following steps:

1. Assign routing to one load following the steps provided in Entering Assign Routing Mode, page 112 above.

2. Assign routing to all the branches of the net.

The figure below shows an example of a net that has assigned routing to one load and requires routing to two additional loads.

Figure 3-20: Assign Branching Route
**Assigning Routing to a Branch**

To assign routing to a branch:

1. Go to Device View.
2. Select the net to be routed.
3. Right-click and select **Enter Assign Routing Mode**.

   The Target Load Cell Pin window opens, showing all loads.

   **Note:** The loads that already have assigned routing have a checkmark in the Routed column of the table.

4. Select the load to which you want to route.

5. Click **OK**. The Branch Start window (shown in the figure below) opens.

   ![Target Load Cell Pin (Multiple Loads)](image)

   **Figure 3-21:**  Target Load Cell Pin (Multiple Loads)
6. Select the node from which you want to branch off the route for your selected load.
7. Click **OK**.
8. Follow the steps shown in Assigning Routing Nodes, page 117.

**Directed Routing Constraints**

Fixed route assignments are stored as Directed Routing Strings in the route database. In a Directed Routing String, branching is indicated by nested (curly braces).

For example, consider the route described in Figure 3-23, below. In this simplified illustration of a route, the various elements are indicated as shown in the following table (Directed Routing Constraints).

<table>
<thead>
<tr>
<th>Elements</th>
<th>Indicated By</th>
</tr>
</thead>
<tbody>
<tr>
<td>Driver and Loads</td>
<td>Orange Rectangles</td>
</tr>
<tr>
<td>Nodes</td>
<td>Red lines</td>
</tr>
<tr>
<td>Switchboxes</td>
<td>Blue rectangles</td>
</tr>
</tbody>
</table>

A simplified version of a Directed Routing String for that route is as follows:

\[(A \ (D \ E \ T \) \ C \ (F \ G \ H \ I \ M \ N) \ (O \ P \) \ R \ J \ K \ L \ S)\].

The route branches at B and C. The main trunk of this route is A B C R J K L S.
Chapter 3: Analyzing and Viewing Implementation Results

Modifying Logic

Properties on logical objects that are not Read Only can be modified after Implementation in the Vivado IDE as well as Tcl.

Note: For more information about Tcl commands, see the Vivado Design Suite Tcl Command Reference Guide (UG835) [Ref 15], or type `<command> -help`.

To modify a property on an object in Device View:

1. Select the object.
2. Modify the property value of the object in the Properties section of the Properties window.
These properties can include everything from Block RAM INITs to the clock modifying properties on MMCMs. There is also a special dialog box to set or modify INIT on LUT objects. This dialog box allows you to specify the LUT equation and have the tools determine the appropriate INIT.
Saving Modifications

To capture the changes to the design made in memory, write a checkpoint of the design. Because the assignments are not back-annotated to the design, you must add the assignments to the XDC for them to impact the next run.

To save the constraints to your constraints file in Project Mode, select **File > Save Constraints**.
Using Remote Hosts and LSF

Launching Runs on Remote Linux Hosts

Overview

The Xilinx® Vivado® Integrated Design Environment (IDE) supports simultaneous parallel execution of synthesis and implementation runs on multiple Linux hosts. You can accomplish this using LSF (Load Sharing Facility) or through manual host configuration.

For instructions on configuring remote hosts with LSF, see Configuring Remote Hosts Using LSF, page 127.

For instructions on configuring remote hosts manually, see Configuring Remote Hosts Manually, page 130.

About LSF

LSF is a subsystem for submitting, scheduling, executing, monitoring, and controlling a workload of batch jobs across compute servers in a cluster. You use the bsub command to launch synthesis and implementation runs in the Vivado Design Suite through LSF.

Linux and Remote Host Support

Linux is the only operating system supporting remote hosts because of:

• Superior security handling in Linux
• The lack of remote-shell capabilities on Microsoft Windows systems

Job Submission Algorithms and SSH

Job submission algorithms are implemented using a “greedy,” round-robin style with Tcl pipes within Secure Shell (SSH), a service within the Linux operating system.
**Appendix A: Using Remote Hosts and LSF**

**RECOMMENDED:** Before launching runs on multiple Linux hosts using manual configuration in the Vivado IDE, configure SSH so that the host does not require a password each time you launch a remote run.

For instructions on configuring SSH, see Setting Up SSH Key Agent Forward, page 132.

**Launch Requirements**

The requirements for launching synthesis and implementation runs on remote Linux hosts are:

- Vivado tools installation is assumed to be available from the login shell, which means that `$XILINX_VIVADO` and `$PATH` are configured correctly in your `.cshrc`/.bashrc setup scripts.

  For Manual Configuration: if you do not have Vivado set up upon login (CSHRC or BASHRC), use the Run pre-launch script option, as described below, to define an environment setup script to be run prior to all jobs.

- Vivado IDE installation must be visible from the mounted file systems on remote machines. If the Vivado IDE installation is stored on a local disk on your own machine, it might not be visible from remote machines.

- Vivado IDE project files (.xpr) and directories (.data and .runs) must be visible from the mounted file systems on remote machines. If the design data is saved to a local disk, it might not be visible from remote machines.

**Configuring Remote Hosts Using LSF**

To configure the Vivado IDE to run synthesis or implementation on a remote Linux host using LSF configuration:

1. Select one of the following commands:
   - From the main menu, **Tools > Options > Remote Hosts**
   - From the **Launch Selected Runs** dialog box, **Configure LSF**
   - From the **Create New Runs** dialog box, **Configure LSF**
The figure below shows the Launch Selected Runs dialog box with the LSF option selected.

![Launch Selected Runs dialog box with LSF option selected]

*Figure A-1:* Configure LSF from Launch Synthesis and Launch Implementation Runs
2. As shown in the figure below, the Vivado Options dialog box displays, with the Remote Hosts section selected. Select the LSF Configuration tab.

![Vivado Options Dialog Box with Remote Hosts Selected](image)

*Figure A-2: Vivado Options Dialog Box with Remote Hosts Selected*

3. *(Optional)* Modify the command line to change `bsub` command options.

   The default command:
   
   ```
   bsub -R select[type=X86_64] -N -q medium
   ```

4. *(Optional)* Click **Test Connection** to test connection to the LSF.

   This executes a special `bsub` procedure to check that:
   
   - Vivado is able to submit a job via LSF.
   - The remote host has access to the runs directory.

   **Note:** When canceling a run, the Vivado tools typically send a `bkill` command with the job id. If this does not occur, you can cancel a run manually from the command line. Type `bkill <jobID>`.
Configuring Remote Hosts Manually

To configure the Vivado IDE to run synthesis or implementation on a remote Linux host:

1. Select one of the following commands:

   - From the main menu, **Tools > Options > Remote Hosts**
   - From the **Launch Selected Runs** dialog box, **Configure Hosts**
   - From the **Create New Runs** dialog box, **Configure Hosts**

The figure below shows the Launch Selected Runs dialog box with the *Launch runs on remote hosts* option selected.

![Launch Selected Runs dialog box](image)

*Figure A-3: Configure Hosts from Launch Synthesis and Launch Implementation Runs*
2. As shown in the figure below, the Vivado Options dialog box appears, with the Remote Hosts section selected. Click the **Manual Configuration** tab to see the list of currently defined remote Linux hosts.

![Vivado Options dialog box](image)

*Figure A-4: Configuring Remote Hosts*

3. Click **Add** to enter the names of additional remote servers.

4. Specify the number of processors the remote machine has available to run simultaneous processes using the **Jobs** field next to the host name. Individual runs require a separate processor.

5. Toggle **Enabled** to specify whether the server is available. Use this field when launching runs to specify which servers to use for selected runs.

6. *(Optional)* Modify **Launch jobs with** to change the remote access command used when launching runs. The default command is:

   ```
   ssh -q -o BatchMode=yes
   ```
IMPORTANT: Use caution when modifying this field. For example, removing **BatchMode =yes** might cause the remote process to hang because the Secure Shell incorrectly prompts for an interactive password.

7. *(Optional)* Check **Run pre-launch script** and define a shell script to run before launching the runs. Use this option to run host environment setup script if you do not have Vivado IDE set up upon login.

8. *(Optional)* Check **Run post-completion script** and define a custom script to run after the run completes, to move or copy the results for example.

9. *(Optional)* Check **Send email to** and enter an Email address to send a notification when the runs complete. You can have notifications sent **After each Job**, or **After all jobs**.

10. Click **OK** to accept the Remote Host configuration settings.

11. Select one or more hosts.

12. Click **Test**.

The tools verify that the server is available and that the configuration is properly set.

**RECOMMENDED:** Test each host to ensure proper setup before submitting runs to the host.

**Removing Remote Hosts**

To remove a remote host:

1. Select the remote host.

2. Click **Remove**.

**Setting Up SSH Key Agent Forward**

SSH configuration is accomplished with the following commands at a Linux terminal or shell:

**Note:** This is a one-time step. When successfully set-up, this step does not need to be repeated.

1. Run the following command at a Linux terminal or shell to generate a public key on your primary machine. Though not required, it is a good practice to enter (and remember) a private key phrase when prompted for maximum security.

   `ssh-keygen -t rsa`

2. Append the contents of your publish key to an **authorized_keys** file on the remote machine. Change **remote_server** to a valid host name:

   `cat ~/.ssh/id_rsa.pub | ssh remote_server "cat - >> ~/.ssh/authorized_keys"`
Appendix A: Using Remote Hosts and LSF

3. Run the following command to prompt for your private key pass phrase, and enable key forwarding:

   ssh-add

You should now be able to `ssh` to any machine without typing a password. The first time you access a new machine, it prompts you for a password. It does not prompt upon subsequent access.

---

**TIP:** If you are always prompted for a password, contact your System Administrator.
Appendix B

ISE Command Map

Tcl Commands and Options

Some command line options in the Xilinx® Vivado® Integrated Design Environment (IDE) implementation are one-to-one equivalents of Xilinx Integrated Software Environment (ISE®) Design Suite commands.

Table B-1 lists various ISE tool command line options, and their equivalent Vivado Design Suite Tcl command and Tcl command options.

Note: For more information about Tcl commands, see the Vivado Design Suite Tcl Command Reference Guide (UG835) [Ref 15], or type <command> -help.
