Introduction

Overview

This tutorial covers the Partial Reconfiguration (PR) software support in Vivado® Design Suite release 2015.1. The tutorial steps through basic information about the current Partial Reconfiguration (PR) design flow, example Tcl scripts, and shows results within the Vivado integrated design environment (IDE). You run scripts for part of the tutorial and work interactively with the design for other parts. You can also script the entire flow, and a completed script is included with the tutorial files. The focus of this tutorial is specifically the software flow from RTL to bitstream, demonstrating how to process a Partial Reconfiguration design. For more information about design considerations and techniques, further details about the commands and constraints, and other aspects of building a partially reconfigurable design, see the Vivado Design Suite User Guide: Partial Reconfiguration (UG909).

TRAINING: Xilinx provides training courses that can help you learn more about the concepts presented in this document. Use the link to explore related courses:

- Xilinx Partial Reconfiguration Tools & Techniques

Hardware and Software Requirements

This tutorial requires that the 2015.1 Vivado Design Suite software release or later is installed.

For Operating Systems support, see the Vivado Design Suite User Guide: Release Notes, Installation, and Licensing (UG973) for a complete list and description of the system and software requirements.

This tutorial targets the Xilinx KC705 demonstration board, Rev 1.0 or 1.1.
Tutorial Design Description

The sample design used throughout this tutorial is called `led_shift_count`. The design targets an xc7k325t device for use on the KC705 demonstration board. This design is very small, which (1) helps minimize data size and (2) allows you to run the tutorial quickly, with minimal hardware requirements.

_TIP:_ The software flow shown here applies to all supported devices, but the floorplanning techniques and bit file details are specific to 7 series devices. For more details on UltraScale device requirements, see the Vivado Design Suite User Guide: Partial Reconfiguration (UG909).
Lab: Partial Reconfiguration

Step 1: Extract the Tutorial Design Files

1. Download the Reference Design Files from the Xilinx website.
2. Extract the zip file contents to any write-accessible location. The unzipped led_shift_count data directory is referred to in this tutorial as the <Extract_Dir>.

Step 2: Examine the Scripts

Start by reviewing the scripts provided in the design archive. The files design.tcl and design_complete.tcl are located at the root level. Both files contain the same information, but design.tcl has parameters set such that only synthesis runs, while design_complete.tcl runs the entire flow for two configurations.

The Main Script

In the <Extract_Dir>, open design.tcl in a text editor. This is the master script where you define the design parameters, design sources, and design structure. This is the only file you have to modify to compile a complete Partial Reconfiguration design. Find more details regarding design.tcl and the underlying scripts in the README.txt located in the Tcl subdirectory.

Note the following details in this file:

- Visualization scripts are requested via the use of set_param hd.visual 1 (on line 5, the set_param command is called in run.tcl). This command creates scripts in the root directory that you use later in the tutorial to identify the frames to be included in the partial bitstreams.
- Under flow control, you can control what phases of synthesis and implementation are run. In the tutorial, only synthesis is run by the script; implementation, verification, and bitstream generation are run interactively. To run these additional steps via the script, set the flow variables (e.g., run.prImpl) to 1.
- The Output Directories and Input Directories set the file structure expected for design sources and results files. You must reflect any changes to your file structure here.
- The Top Definition and RP Module Definitions sections allow you to reference all source files for each part of your design. Top Definition covers all sources needed for the static design, including constraints and IP. The RP Module Definitions section does the same for Reconfigurable Partitions (RP). Complete a section for each RP and list all Reconfigurable Module (RM) variants for each RP.
This design has two Reconfigurable Partitions (inst_shift and inst_count), and each RP has two module variants.

- The Configuration Definition sections define the sets of static and reconfigurable modules that make up a configuration.
- This design has two configurations, Config_shift_right_count_up and Config_shift_left_count_down. You can create more configurations by adding RMs or by combining existing RMs.

**The Supporting Scripts**

Underneath the Tcl subdirectory, several supporting Tcl scripts exist. The scripts are called by design.tcl, and they manage specific details for the Partial Reconfiguration flow. Provided below are some details about a few of the key PR scripts.

---

**CAUTION! Do not modify the supporting Tcl scripts.**

---

- step.tcl
  Manages the current status of the design by monitoring checkpoints.
- synth.tcl
  Manages all the details regarding the synthesis phase.
- impl.tcl
  Manages all the details regarding the module implementation phase.
- pr_impl.tcl
  Manages all the details regarding the top-level implementation of a PR design.
- run.tcl
  Launches the actual runs for synthesis and implementation.
- log.tcl
  Handles report file creation at key points during the flow.

Remaining scripts provide details within these scripts (such as the *_utils.tcl scripts) or manage other Hierarchical Design flows (such as ooc_impl.tcl).
Step 3: Synthesize the Design

The design.tcl script automates the synthesis phase of this tutorial. Five iterations of synthesis are called, one for the static top-level design and one for each of four Reconfigurable Modules.

1. Open the Vivado Tcl shell:
   - On Windows, select the Xilinx Vivado desktop icon or Start > All Programs > Xilinx Design Tools> Vivado 2015.1 > Vivado 2015.1 Tcl Shell.
   - On Linux, simply type, vivado -mode tcl.
2. In the shell, navigate to the <Extract_Dir> directory.
3. Run the design.tcl script by entering:
   
   `source design.tcl -notrace`

After all five passes through Vivado Synthesis have completed, the Vivado Tcl shell is left open. You can find log and report files for each module, alongside the final checkpoints, under each named folder in the Synth subdirectory.

**TIP:** In the <Extract_Dir> directory, multiple log files have been created:
- run.log shows the summary as posted in the Tcl shell window
- command.log echoes all the individual steps run by the script
- critical.log reports all critical warnings produced during the run

Step 4: Assemble the Design

Now that the synthesized checkpoints for each module, plus top, are available, you can assemble the design. Because project support for Partial Reconfiguration flows is not yet in place, you do not use the project infrastructure from within the IDE.

You will run all flow steps from the Tcl Console, but you can use features within the IDE (such as the floorplanning tool) for interactive events.

**TIP:** Copy and paste commands directly from this document to avoid redundant effort and typos in the Vivado IDE. Copy and paste only one full command at a time. Note that some commands are long and therefore span multiple lines.
Implement the Design

1. Open the Vivado IDE. You can open the IDE from the open Tcl shell by typing `start_gui` or by launching Vivado with the command `vivado -mode gui`.

2. Navigate to the `<Extract_Dir>` directory if you are not already there. The `pwd` command can confirm this.

3. Load the static design by issuing the following command in the Tcl Console:
   ```tcl
   open_checkpoint Synth/Static/top_synth.dcp
   ```
   You can see the design structure in the Netlist pane, but black boxes exist for the `inst_shift` and `inst_count` modules. Note that the Flow Navigator pane is not present. You are working in non-project mode.

   **TIP:** Place the IDE in floorplanning mode by selecting **Layout > Floorplanning**.
   Make sure the Device view is visible

   Two critical warnings are issued regarding unmatched instances. These instances are the Reconfigurable Modules that have yet to be loaded, and you can therefore ignore these warnings safely.

4. Load the synthesized checkpoints for first Reconfigurable Module variants for each of reconfigurable partitions:
   ```tcl
   read_checkpoint -cell inst_shift Synth/shift_right/shift_synth.dcp
   read_checkpoint -cell inst_count Synth/count_up/count_synth.dcp
   ```
   Note that the `inst_shift` and `inst_count` modules have been filled in with logical resources. You can now traverse the entire hierarchy within the Netlist pane.

5. Define each of these submodules as partially reconfigurable by setting the `HD.RECONFIGURABLE` property:
   ```tcl
   set_property HD.RECONFIGURABLE 1 [get_cells inst_shift]
   set_property HD.RECONFIGURABLE 1 [get_cells inst_count]
   ```
   This is the point at which the Partial Reconfiguration license is checked. If you have a valid license, you see this message:
   ```
   Feature available: PartialReconfiguration
   ```
   If you have no license with the PartialReconfiguration feature, contact your local Xilinx sales office for more information. Evaluation licenses are available.

6. Save the assembled design state for this initial configuration:
   ```tcl
   write_checkpoint ./Checkpoint/top_link_right_up.dcp
   ```
Step 5: Build the Design Floorplan

Next, you must create a floorplan to define the regions that will be partially reconfigured.

1. Select the inst_count instance in the Netlist pane. Right click and select **Floorplanning > Draw Pbloc**k and draw a tall narrow box on the left side of the X0Y3 clock region. The exact size and shape do not matter at this point, but keep the box within the clock region.

   ![Figure 1: Pblock for the inst_count Reconfigurable Partition](image)

   Although this Reconfigurable Module only requires CLB resources, also include RAMB16, RAMB32, or DSP48 resources if the box encompasses those types. This allows the routing resources for these block types to be included in the reconfigurable region. The **General** tab of the Pblock Properties pane can be used to add these if needed. The **Statistics** tab shows the resource requirements of the currently loaded Reconfigurable Module.

2. In the Properties pane, select the checkbox for **RESET_AFTER_RECONFIG**. This will utilize the dedicated initialization of the logic in this module after reconfiguration has completed.
3. Repeat steps 1 and 2 for the inst_shift instance, this time targeting the right side of clock region X1Y1. This Reconfigurable Module includes block RAM instances, so the resource type must be included. If omitted, the RAMB details in the Statistics tab will be shown in red.

![Figure 2: Pblock for the inst_shift Reconfigurable Partition](image)

4. Run Partial Reconfiguration Design Rule Checks by selecting Tools > Report > Report DRC. You can uncheck All Rules and then check Partial Reconfiguration to focus this report strictly on PR DRCs.
Figure 3: Partial Reconfiguration Design Rule Checks (DRCs)
One or two DRCs will be reported at this point, and there are two ways of resolving them. We will use one method for inst_shift and the other for inst_count.

The first DRC will be an error, HDPR-10, reporting that RESET_AFTER_RECONFIG requires Pblock frame alignment.

5. To resolve the first DRC error, make sure that the height of the Pblock aligns with the clock region boundaries. Using the Pblock for inst_shift, stretch the top and bottom edges to match the clock region boundaries of X1Y1 as shown in the figure below. Note that the shading of the Pblock is now more uniform.

![Figure 4: Pblock for the aligned inst_shift Reconfigurable Partition](image)

The other possible DRC is a warning, HDPR-26, reporting that a left or right edge of a reconfigurable Pblock terminates on an improper boundary. Left or right edges must not split interconnect (INT) columns. More information on this requirement can be found in the Vivado Design Suite User Guide: Partial Reconfiguration (UG909), in the section entitled Reconfigurable Partition Pblock Sizes and Shapes.
6. To manually avoid this DRC warning, zoom into the upper or lower corner on the reported edge of inst_shift (or inst_count, if inst_shift did not report an issue) to see where the violation has occurred. Move this edge left or right one column, as shown by the yellow arrows in Figure 5, so it lands between two resource types (CLB-CLB or CLB-RAMB, for example) instead landing between CLB-INT or BRAM-INT.

![Figure 5: Adjusting the Edges of a Reconfigurable Pblock](image)

7. Run the PR DRCs again to confirm that the errors and warnings that you have addressed have been resolved for the inst_shift instance.

An alternative to manually adjusting the size and shape of reconfigurable Pblocks is to use the SNAPPING_MODE feature. This feature automatically adjusts edges to align with legal boundaries. It will make the Pblock taller, aligning with clock region boundaries, if the RESET_AFTER_RECONFIG feature is selected. It will make the Pblock narrower, adjusting left and/or right edges as needed. Note that the number and type of resources available will be altered if SNAPPING_MODE makes changes to the Pblock.

8. Select the Pblock for inst_count, and in the Properties tab of the Pblock Properties pane, change the value of SNAPPING_MODE from OFF to ON.
Note that the original Pblock does not change. The adjustments to the Pblock needed for it to conform to PR rules are done automatically, without modifying your source constraints.

9. Run the PR DRCs once again to confirm that all issues have been resolved.

10. Save these Pblocks and associated properties by issuing this command in the Tcl Console:

   ```tcl
   write_xdc ./Sources/xdc/fplan.xdc
   ```

   This will export all the current constraints in the design. These constraints can be managed in their own XDC file, merged with another XDC file (such as top_io.xdc), or managed within a run script (as is typically done with HD.RECONFIGURABLE).

Now that the floorplan has been established, you will implement the design.

---

**Step 6: Implement the First Configuration**

In this step you will place and route the design and prepare the static portion of the design for reuse with new Reconfigurable Modules.

1. Load the top-level constraint file by issuing the command:

   ```tcl
   read_xdc Sources/xdc/top_io.xdc
   ```

   This sets the device pinout and top-level timing constraints. This XDC file is not accessible from the IDE – it will not appear as a design source.

   This top-level XDC file should only contain constraints that reference objects in the static design. Constraints for logic or nets inside of the RP can be applied for specific Reconfigurable Modules if needed.

2. Optimize, place, and route the design by issuing the following commands:

   ```tcl
   opt_design
   place_design
   route_design
   ```

   After both `place_design` and `route_design`, examine the state of the design in the Device view (See Figure 6). One thing to note after `place_design` is the introduction of Partition Pins. These are the physical interface points between static and reconfigurable logic and are the replacement in Vivado for what was Proxy Logic in ISE. They are anchor points within an interconnect tile through which each I/O of the Reconfigurable Module must route. They appear as white boxes in the placed design view. For `pblock_shift`, they appear in the top of that Pblock, as the connections to static are just outside the Pblock in that area of the device. For `pblock_count`, they appear outside the user-defined region, as SNAPPING_MODE has vertically collected more frames to be added to the Reconfigurable Partition.
3. To find these partition pins in the GUI easily:
   a. Select the Reconfigurable Module (e.g., \texttt{inst\_shift}) in the Netlist pane.
   b. Select the \textbf{Cell Pins} tab in the Cell Properties pane.
4. Select any pin to highlight it, or use Ctrl+A to select them all. The Tcl equivalent of the latter is:
   \begin{verbatim}
   select_objects [get_pins inst\_shift/*]
   \end{verbatim}
5. In the routed design view, click the \textbf{Show/Hide Nets} icon \includegraphics[width=5cm]{showhide_nets.png} to display all routes by type (Fully Routed, Partially Routed, or Unrouted), as shown in \textbf{Figure 7}. Use the Routing Resources icon \includegraphics[width=5cm]{routing_resources.png} to toggle between abstracted and actual routing information, and to change the visibility of the routing resources themselves. All nets in the design are fully routed at this point.
Save the Results

6. Save the full design checkpoint and create report files by issuing these commands:

   ```
   write_checkpoint -force Implement/Config_shift_right_count_up/top_route_design.dcp
   report_utilization -file Implement/Config_shift_right_count_up/top_utilization.rpt
   report_timing_summary -file Implement/Config_shift_right_count_up/top_timing_summary.rpt
   ```

7. [Optional] Save checkpoints for each of the Reconfigurable Modules by issuing these two commands:

   ```
   write_checkpoint -force -cell inst_shift Checkpoint/shift_right_route_design.dcp
   write_checkpoint -force -cell inst_count Checkpoint/count_up_route_design.dcp
   ```

   **TIP:** When running `design_complete.tcl` to process the entire design in batch mode, design checkpoints, log files, and report files are created at each step of the flow.

At this point, you have created a fully implemented partial reconfiguration design from which you can generate full and partial bitstreams. The static portion of this configuration is used for all subsequent configurations, and to isolate the static design, the current Reconfigurable Modules must be removed.
8. Make sure routing resources are enabled, and zoom in to an interconnect tile with partition pins.

9. Clear out Reconfigurable Module logic by issuing the following commands:

\[
\text{update\_design \texttt{-cell inst\_shift \texttt{-black\_box}}}
\]
\[
\text{update\_design \texttt{-cell inst\_count \texttt{-black\_box}}}
\]

Issuing these commands results in many design changes as shown in the figure below:

- The number of Fully Routed nets (green) has decreased.
- \texttt{inst\_shift} and \texttt{inst\_count} now appear in the Netlist view as empty.

![Figure 8: The \texttt{inst\_shift} module before (top) and after (bottom) update\_design \texttt{-black\_box}](image-url)
10. Issue the following command to lock down all placement and routing:

```
lock_design -level routing
```

Because no cell was identified in the `lock_design` command, the entire design in memory (currently consisting of the static design with black boxes) is affected. All routed nets are now displayed as locked, as indicated by dashed lines in the figure below. All placed components changed from blue to orange to show they are also locked.

![Figure 9: Close-up of Static-Only Design with Locked Routing](image)

11. Issue the following command to write out the remaining static-only checkpoint:

```
write_checkpoint -force Checkpoint/static_route_design.dcp
```

This static-only checkpoint would be used for any future configurations. In this tutorial, however, you simply keep this design open in memory.
Step 7: Implement the Second Configuration

The static design result is now established and locked, and you will use it as context for implementing further Reconfigurable Modules.

**Implement the Design**

1. With the locked static design open in memory, read in post-synthesis checkpoints for the other two Reconfigurable Modules.

   ```
   read_checkpoint -cell inst_shift Synth/shift_left/shift_synth.dcp
   read_checkpoint -cell inst_count Synth/count_down/count_synth.dcp
   ```

2. Optimize, place and route the new RMs in the context of static by issuing these commands:

   ```
   opt_design
   place_design
   route_design
   ```

   The design is again fully implemented, now with the new Reconfigurable Module variants. The routing is a mix of dashed (locked) and solid (new) routing segments, as shown below.

![Figure 10: Second Configuration Routed, Showing Locked and New Routes](image-url)
Save Results

3. Save the full design checkpoint and report files by issuing these commands:

   ```
   write_checkpoint -force Implement/Config_shift_left_count_down/top_route_design.dcp
   report_utilization -file Implement/Config_shift_left_count_down/top_utilization.rpt
   report_timing_summary -file Implement/Config_shift_left_count_down/top_timing_summary.rpt
   ```

4. [Optional] Save checkpoints for each of the Reconfigurable Modules by issuing these two commands:

   ```
   write_checkpoint -force -cell inst_shift Checkpoint/shift_left_route_design.dcp
   write_checkpoint -force -cell inst_count Checkpoint/count_down_route_design.dcp
   ```

At this point, you have implemented the static design and all Reconfigurable Module variants. This process would be repeated for designs that have more than two Reconfigurable Modules per Reconfigurable Partition.

---

Step 8: Examine Results

Use Highlighting Scripts

With the routed configuration open in the IDE, run some visualization scripts to highlight tiles and nets. These scripts identify the resources allocated for partial reconfiguration, and are automatically generated when the `hd.visual` parameter is enabled.

1. In the Tcl Console, issue the following commands from the `<Extract_Dir>` directory:

   ```
   source hd_visual/pblock_inst_shift_AllTiles.tcl
   highlight_objects -color blue [get_selected_objects]
   ```

2. Click somewhere in the Device view to deselect the frames (or enter `unselect_objects`), then issue the following commands:

   ```
   source hd_visual/pblock_inst_count_AllTiles.tcl
   highlight_objects -color yellow [get_selected_objects]
   ```

The partition frames appear highlighted in the Device view, as shown in Figure 11 below.
Figure 11: Reconfigurable Partition Frames Highlighted

These highlighted tiles represent the configuration frames that are sent to bitstream generation to create the partial bitstreams. As shown above, the SNAPPING_MODE feature has adjusted all four edges of pblock_count to account for RESET_AFTER_RECONFIG and legal reconfigurable partition widths.

The other “tile” scripts are variations on these. If you had not created Pblocks that vertically aligned to the clock region boundaries, the FrameTiles script would highlight the explicit Pblock tiles, while the AllTiles script extends those tiles to the full reconfigurable frame height. Note that these leave gaps where unselected frame types (e.g., global clocks) exist.

The GlitchTiles script is a subset of frame sites, avoiding dedicated silicon resources; the other scripts are more informative than this one.

Finally, the Nets scripts are created for Tandem Configuration and do not apply to PR.

3. Close the current design:
   close_project
Step 9: Generate Bitstreams

Verify Configurations

RECOMMENDED: Before generating bitstreams, verify all configurations to ensure that the static portion of each configuration match identically, so the resulting bitstreams are safe to use in silicon. The PR Verify feature examines the complete static design up to and including the partition pins, confirming that they are identical. Placement and routing within the Reconfigurable Modules is not checked, as different module results are expected here.

1. Run the `pr_verify` command from the Tcl Console:
   
   ```
   pr_verify Implement/Config_shift_right_count_up/top_route_design.dcp Implement/Config_shift_left_count_down/top_route_design.dcp
   ```

   If successful, this command returns the following message.

   ```
   INFO: [Vivado 12-3253] PR_VERIFY: check points 
   Implement/Config_shift_right_count_up/top_route_design.dcp and 
   Implement/Config_shift_left_count_down/top_route_design.dcp are compatible 
   ```

   By default, only the first mismatch (if any) is reported. To see all mismatches, use the `-full_check` option.

Generate Bitstreams

Now that the configurations have been verified, you can generate bitstreams and use them to target the KC705 demonstration board.

2. First, read the first configuration into memory:
   
   ```
   open_checkpoint Implement/Config_shift_right_count_up/top_route_design.dcp
   ```

3. Generate full and partial bitstreams for this design. Be sure to keep the bit files in a unique directory related to the full design checkpoint from which they were created.

   ```
   write_bitstream -file Bitstreams/Config_RightUp.bit
   close_project
   ```

Notice the three bitstreams have been created:

- `Config_RightUp.bit`
  This is the power-up, full design bitstream.

- `Config_RightUp_pblock_inst_shift_partial.bit`
  This is the partial bit file for the `shift_right` module.

- `Config_RightUp_pblock_inst_count_partial.bit`
  This is the partial bit file for the `count_up` module.
**IMPORTANT:** The names of the bit files currently do not reflect the name of the Reconfigurable Module variant to clarify which image is loaded. The current solution uses the base name given by the `-file` option and appends the Pblock name of the reconfigurable cell. It is critical to provide enough description in the base name to be able to identify the reconfigurable bit files clearly. All partial bit files have the `_partial` postfix.

4. Generate full and partial bitstreams for the second configuration, again keeping the resulting bit files in the appropriate folder.

   open_checkpoint Implement/Config_shift_left_count_down/top_route_design.dcp
   write_bitstream -file Bitstreams/Config_LeftDown.bit close_project

   Similarly, you see three bitstreams created, this time with a different base name.

5. Generate a full bitstream with black boxes, plus blanking bitstreams for the Reconfigurable Modules. Blanking bitstreams can be used to “erase” an existing configuration to reduce power consumption.

   open_checkpoint Checkpoint/static_route_design.dcp
date_design -cell inst_count -buffer_ports
update_design -cell inst_shift -buffer_ports
place_design
route_design
writeCheckpoint Checkpoint/Config_black_box.dcp
write_bitstream -file Bitstreams/config_black_box.bit close_project

   The base configuration bitstream will have no logic for either reconfigurable partition. The `update_design` commands here insert constant drivers (ground) for all outputs of the Reconfigurable Partitions, so these outputs will not float. The `place_design` and `route_design` commands ensure they are completely implemented.
Step 10: Partially Reconfigure the FPGA

The count_shift_led design targets the KC705 demonstration board. The current design supports board revisions Rev 1.0 and Rev 1.1.

Configure the device with a full image

1. Connect the KC705 to your computer via the Platform Cable USB and power on the board.
2. From the main Vivado IDE, select Flow > Open Hardware Manager.
3. Select Open a new hardware target on the green banner. Follow the steps in the wizard to establish communication with the board.
4. Select Program device on the green banner and pick the XC7K325T_0. Navigate to the Bitstreams folder to select Config_RightUp.bit, then click OK to program the device.
   
   You should now see the bank of GPIO LEDs performing two tasks. Four LEDs are performing a counting-up function (MSB is on the left), and the other four are shifting to the right. Note the amount of time it took to configure the full device.

Partially reconfigure the device

At this point, you can partially reconfigure the active device with any of the partial bitstreams that you have created.

5. Select Program device on the green banner again. Navigate to the Bitstreams folder to select Config_LeftDown_pblock_inst_shift_partial.bit, then click OK to program the device.
   
   The shift portion of the LEDs has changed direction, but the counter kept counting up, unaffected by the reconfiguration. Note the much shorter configuration time.

6. Select Program device on the green banner again. Navigate to the Bitstreams folder to select Config_LeftDown_pblock_inst_count_partial.bit, then click OK to program the device.
   
   The counter is now counting down, and the shifting LEDs were unaffected by the reconfiguration. This process can be repeated with the Config_RightUp partial bit files to return to the original configuration, or with the blanking partial bit files to stop activity on the LEDs (they will stay on).
Conclusion

In this tutorial, you:

- Synthesized a design bottom-up to prepare for partial reconfiguration implementation
- Created a valid floorplan for a partial reconfiguration design
- Created two configurations with common static results
- Implemented these two configurations, saving the static design to be used in each
- Created checkpoints for static and reconfigurable modules for later reuse
- Examined framesets and verified the two configurations
- Created full and partial bitstreams
- Configured and partially reconfigured an FPGA

Please Read: Important Legal Notices

The information disclosed to you hereunder (the “Materials”) is provided solely for the selection and use of Xilinx products. To the maximum extent permitted by applicable law: (1) Materials are made available “AS IS” and with all faults, Xilinx hereby DISCLAIMS ALL WARRANTIES AND CONDITIONS, EXPRESS, IMPLIED, OR STATUTORY, INCLUDING BUT NOT LIMITED TO WARRANTIES OF MERCHANTABILITY, NONINFRINGEMENT, OR FITNESS FOR ANY PARTICULAR PURPOSE; and (2) Xilinx shall not be liable (whether in contract or tort, including negligence, or under any other theory of liability) for any loss or damage of any kind or nature related to, arising under, or in connection with, the Materials (including your use of the Materials), including for any direct, indirect, special, incidental, or consequential loss or damage (including loss of data, profits, goodwill, or any type of loss or damage suffered as a result of any action brought by a third party) even if such damage or loss was reasonably foreseeable or Xilinx had been advised of the possibility of the same. Xilinx assumes no obligation to correct any errors contained in the Materials or to notify you of updates to the Materials or to product specifications. You may not reproduce, modify, distribute, or publicly display the Materials without prior written consent. Certain products are subject to the terms and conditions of Xilinx’s limited warranty, please refer to Xilinx’s Terms of Sale which can be viewed at http://www.xilinx.com/legal.htm#tos; IP cores may be subject to warranty and support terms contained in a license issued to you by Xilinx. Xilinx products are not designed or intended to be fail-safe or for use in any application requiring fail-safe performance; you assume sole risk and liability for use of Xilinx products in such critical applications, please refer to Xilinx’s Terms of Sale which can be viewed at http://www.xilinx.com/legal.htm#tos.
